## TECHNOLOGY

# The First-Ever Banner Ad on the Web

It was an advertisement for AT&T in 1994, and people clicked on it like crazy.

ADRIENNE LAFRANCE APRIL 21, 2017

KATIE MARTIN / THE ATLANTIC

People don't often click on banner ads these days—at least not on purpose, anyway. In fact, many internet users actively go out of their way to never see advertisements.

Ad blockers create all kinds of problems for companies that rely on ad dollars to pay their workers (cough cough like journalists cough), but it's understandable why ad blockers appeal to people. Display ads are too often clunky, ugly, and intrusive—all kinds of ad trackers collect and sell data about people.

All this is part of why reports that Google will make ad blocking part of its Chrome web browser are so ominous: Google, the largest beneficiary of web advertising on the planet, wants to block ads that help anybody else make money.

How did we get here?

There was a time, in another century, when people used to click on banner ads. Back when they were still a novelty some 20 years ago, people even shared links to banner ads—or, at least, to the first one ever, anyway. The banner ad that's widely described as the first ever was a little rectangle purchased by AT&T on HotWired.com in 1994. About 44 percent of the people who saw it actually clicked on it.

Here's what the first banner ad looked like (HotWired / AT&T)

The ad set off a chain reaction that altered the course of the advertising industry—and any other industry that overlapped with it. ("It's almost like a prank that was played by the technology industry on the media industry 20 years ago," Chris Dixon, the tech investor, told *The New York Times* in 2014.)

The first banner ad was part of AT&T's larger "You Will" campaign, which included a series of television commercials featuring predicted scenes from an internet-enabled

future—in many cases quite accurately. (One failure: AT&T predicted video calling, but not mobile video calling, imaging FaceTime taking place in a phone booth.)

### AT&T 1993 "You Will" Ads

According to *Wired*, HotWired had 14 additional banner ads ready to go from other companies—including Club Med, 1-800-Collect, and Zima—but AT&T just happened to be the first.

Banner ads caught on quickly. In 1995, Yahoo announced an advertising deal for their own primitive banner ads—with the logos of five sponsor companies rotating daily atop Yahoo's site. By the time the Internet Archive's Wayback Machine captured the first glimpse of HotWired, in 1997, there were multiple advertisements on the site, including display ads for discount PCs and data centers. The real problem for HotWired's ad agency at the time, Ryan Singel wrote for *Wired* in 2010, "was realizing that banner ads would be clickable, so it had to create websites for its clients, who

weren't even sure that interacting online was a good idea—or that the ads were even legal.”

When people clicked AT&T's 1994 banner ad, they wound up at a simple landing page that offered more information about AT&T. The answer to “Have you ever clicked your mouse right here?” became, on the new page, “You did! Now let's see what else you'll do.”

The First Ever Banner Ad on The Web / The Atlantic  
The landing page that users saw when they clicked on the first banner ad. (AT&T / Craig Kanarick)

Ads dramatically changed the early web, including the way companies operated and how websites themselves looked. You can see this evolution clearly, thanks to the web designer Jeffrey Veen's catalogue of how HotWired.com changed in appearance from 1994 to 1999, when it was owned by Lycos and leveraged for monetized clicks. HotWired split off from the print magazine, *Wired*, when Condé Nast bought Wired for \$80 million in 1998. That transaction took place after years of speculation that *Wired* might go public.

Well before that, by 1996, people were already complaining about cyberspace's new billboards as "boring and ineffective," according to *The New York Times* that year. Today's display ads fare even worse, with a clickthrough rate of about .05 percent, according to the marketing research firm SmartInsights.

"Banner ads didn't always suck," Joe McCambley, who helped design the AT&T ad in 1994, wrote for Harvard Business Review. "My children tell me that's like inventing smallpox."

The person who created the first pop-up ad is similarly sheepish about what he wrought. "I'm sorry," Ethan Zuckerman, who coded the first pop-up ad, wrote for *The Atlantic* in 2014. "Our intentions were good."

Advertisers liked pop ups, he once told me, because they created a distinction between the advertisement and whatever was on the webpage where the ad appeared. The funny thing is, as display advertising falls away, that distinction is collapsing in other ways. Increasingly, brands want to be perceived as storytellers and publishers in their own right.

(57) **ABSTRACT**

A method for presenting advertising in an interactive service provided on a computer network, the service featuring applications which include pre-created, interactive text/graphic sessions is described. The method features steps for presenting advertising concurrently with service applications at the user terminal configured as a reception system. In accordance with the method, the advertising is structured in a manner comparable to the service applications enabling the applications to be presented at a first portion of a display associated with the reception system and the advertising presented at a second portion. Further, steps are provided for storing and managing advertising at the user reception system so that advertising can be pre-fetched from the network and staged in anticipation of being called for presentation. This minimizes the potential for communication line interference between application and advertising traffic and makes the advertising available at the reception system so as not to delay presentation of the service applications. Yet further the method features steps for individualizing the advertising supplied to enhance potential user interest by providing advertising based on a characterization of the user as defined by the users interaction with the service, user demographics and geographical location. Yet additionally, advertising is provided with transactional facilities so that users can interact with it.

**METHOD FOR PRESENTING ADVERTISING  
IN AN INTERACTIVE SERVICE****RELATED APPLICATIONS**

This is a division of application Ser. No. 07/388,156 filed Jul. 28, 1989, Sep. 13, 1994, as U.S. Pat. No. 5,347,632, application Ser. No. 07/388,156 being a continuation in part of application Ser. No. 07/328,790, now abandoned filed Mar. 23, 1989, which itself was a continuation in part of application Ser. No. 07/219,931, now abandoned filed Jul. 15, 1988.

**BACKGROUND OF THE INVENTION****1. Field of Use**

This invention relates generally to a distributed processing, interactive computer network intended to provide very large numbers of simultaneous users; e.g. millions, access to an interactive service having large numbers; e.g., thousands, of applications which include pre-created, interactive text/graphic sessions; and more particularly, to a method for presenting advertising to service users during interactive sessions, the method featuring steps for presenting advertising concurrently with applications, the advertising being organized as data which is stored for presentation and replenished at the user sites so as to minimize interference with retrieval and presentation of application data; the method also featuring steps for individualizing the advertising presented based on user characterizations defined by service interaction and/or other data such as user demographics and geographical location.

**2. Prior Art**

Interactive computer networks are not new. Traditionally they have included conventional, hierarchical architectures wherein a central, host computer responds to the information requests of multiple users. An illustration would be a time-sharing network in which multiple users, each at a remote terminal, log onto a host that provides data and software resource for sequentially receiving user data processing requests, executing them and supplying responses back to the users.

While such networks have been successful in making the processing power of large computers available to many users, problems have existed with them. For example, in such networks, the host has been required to satisfy all the user data processing requests. As a result, processing bottlenecks arise at the host that cause network slowdowns and compel expansion in computing resources; i.e., bigger and more complex computer facilities, where response times are sought to be held low in the face of increasing user populations.

Host size and complexity, however, are liabilities for interactive networks recently introduced to offer large numbers of the public access to transactional services such as home shopping, banking, and investment maintenance, as well as informational services concerning entertainment, business and personal matters. As can be appreciated, commercial interactive networks will have to provide attractive services at low cost and with minimal response times in order to be successful. Unlike military and governmental networks where, because of the compulsory nature of the service performed, costs, content and efficiency are of secondary concern, in commercial services, since use is predominantly elective, and paid for by the consumer, costs will have to be held low, content made interesting and response times reduced in order to attract and hold both users who

2

would subscribe to the service and merchandisers who would rely on it as a channel of distribution for their good and services. Accordingly, if the service delivery system is allowed to increase in size and complexity, either unchecked or unsubsidized, higher use costs would have to be charged to recover the larger capital and operating expenses, with the negatively, spiralling effect that fewer users could be attracted and be available over which to spread the costs for sustaining the service.

In the past, other suppliers of mass-media services such as radio, television, newspapers, and magazines, have sought to hold access and subscription prices to affordable levels by relying on advertising income to offset the costs of providing their users with the benefits of technological advance. However, in the case of interactive computer services, it has not been apparent how advertising could be introduced without adversely affecting service speed and content quality, which as noted, are considered essential elements for service success.

Particularly, in an interactive service, if advertising were provided in a conventional manner; as for example, by providing the advertising as additional data to be supplied to and presented at the user sites, the effort would compete with the supplying and presentation of service application data, and have the undesirable effect of diminishing service response time. More specifically, if advertising were supplied conventionally from a host to a user site, the application traffic, which constitutes the substance of the service, would have to compete with advertising for network communication resources. Yet additionally, even if traffic conflicts were somehow avoided, the presentation of the service applications would have to be interrupted and delayed; for example like television and radio commercials, as advertising content was presented to the user. The effect of these anticipated delays would be to degrade application response time and diminishing service attractiveness.

Additionally, in view of the need to maintain the user's interest in application content so as to drive the interactive session, it has not been apparent how advertising matter could be provided without distracting the user or disrupting the session. Where service response time is diminished for the sake of advertising which is either irrelevant or distasteful, insult is added to the injury, increasing the likelihood the user, and service, will be, simply, turned off.

**SUMMARY OF INVENTION**

Accordingly, it is an object of this invention to provide a method for presenting advertising in an interactive service.

It is another object of this invention to provide a method for presenting advertising in an interactive service which method enables the presentation of advertising to be integrated with presentation of service applications.

It is a yet another object of this invention to provide a method for presenting advertising in an interactive service which method minimizes the potential for interference between the supply of interactive-service applications and advertising.

It is a still another object of this invention to provide a method for presenting advertising which minimizes the potential for interference between presentation of interactive-service applications and advertising. It is yet a further object of this invention to provide a method for presenting advertising in an interactive service which method enables the advertising presented to be individualized to the user to whom it is presented in order to increase the likelihood the advertising will be of interest to the user.

US 7,072,849 B1

3

And, it is still a further object of this invention to provide a method for presenting advertising in an interactive service which method enables the user to transactionally interact with the advertising presented.

Briefly, the method for presenting advertising in accordance with this invention achieves the above-noted and other objects by featuring steps for presenting advertising concurrently with service applications at the user reception system; i.e., terminal. In accordance with the method, the advertising is structured in a manner comparable to the manner in which the service applications are structured. This enables the applications to be presented at a first portion of a display associated with the reception system and the advertising to be presented concurrently at a second portion of the display. Further, in accordance with the method, the user reception system at which the advertising is presented includes facility for storing and managing the advertising so that it can be pre-fetched from the network and staged at the reception system in anticipation of being called for presentation. This minimizes the potential for communication line interference between application and advertising traffic and makes the advertising available at the reception system so as not to delay presentation of the service applications. Yet further the method features steps for individualizing the advertising supplied to enhance potential user interest by providing advertising based on a characterization of the user as defined by the users interaction with the service, user demographics and geographical location. Yet additionally, advertising is provided with transactional facilities so that users can interact with it.

In preferred form, the method includes step for organizing advertising and applications as objects that collectively include presentation data and executable program instructions for generating the advertising and applications at the reception system. In accordance with the preferred form of the method, advertising and application objects are selectively distributed in the service network in accordance with a predetermined plan based on the likelihood the applications and advertising will be called by the respective user reception systems.

Also in preferred form, the method includes step for maintaining an advertising object identification queue, and an advertising object store that are replenished based on predetermined criteria as advertising is called for association and presentation with applications. In accordance with the method, as applications are executed at the reception system, the application objects provide generalized calls for advertising. The application calls for advertising are subsequently forwarded to the reception system advertising queue management facility which, in turn supplies an identification of advertising who's selection has been individualized to the user based on, as noted, the user's prior interaction history with the service, demographics and local. Thereafter, the object identification for the advertising is passed to the object store to determine if the object is available at the reception system. In preferred form, if the advertising object is not available at the reception system, a sequence of alternative advertising object identifications can be provided which if also are unavailable at the reception system will resulting in an advertising object being requested from the network. In this way, advertising of interest can be targeted to the user and secured in time-efficient manner to increase the likelihood of user interest and avoid service distraction.

4

#### BRIEF DESCRIPTION OF THE DRAWINGS

The above and further objects, features and advantages of the invention will become clear from the following more detailed description when read with reference to the accompanying drawings in which:

FIG. 1 is a block diagram of the interactive computer network in which the method of the present invention may be practiced;

FIG. 2 is a schematic diagram of the network illustrated in FIG. 1;

FIGS. 3a and 3b are plan views of a display screen for a user reception system at which advertising can be presented to a user in accordance with the method of the present invention;

FIGS. 4a, 4b, 4c and 4d are schematic drawings that illustrate the structure of objects, and object segments that may be used for advertising and applications in accordance with the method of the present invention;

FIG. 5a is a schematic diagram that illustrates the configuration of the page template object which might be used for presentation of an application and advertising in accordance with the method of the present invention;

FIG. 5b is a schematic diagram that illustrates page composition which might be used for presentation of an application and advertising in accordance with the method of the present invention;

FIG. 6 is a schematic diagram that illustrates the protocol which might be used by a reception system for supporting applications and advertising in accordance with the method of the present invention;

FIG. 7 is a schematic diagram that illustrates major layers for a reception system which might be used for supporting applications and advertising in accordance with the method of the present invention;

FIG. 8 is a block diagram that illustrates native code modules for a reception system which might be used for supporting applications and advertising in accordance with the method of the present invention;

FIG. 9 is a schematic diagram that illustrates an example of a partitioned application to be processed by a reception system which might be used for supporting applications and advertising in accordance with the method of the present invention;

FIG. 10 illustrates generation of a page with a page processing table for a reception system which might be used for supporting applications and advertising in accordance with the method of the present invention;

FIG. 11 is a flow diagram for an aspect of the navigation method of a reception system which might be used for supporting applications and advertising in accordance with the method of the present invention.

#### DESCRIPTION OF THE PREFERRED EMBODIMENT

##### General System Description

FIGS. 1 and 2 show a network in which the method of the present invention for presenting advertising might be used. As seen the network, designated 10, includes a plurality of reception units within a reception layer 401 for displaying information and providing transactional services. In this arrangement, many users each access network 10 with a conventional personal computer; e.g., one of the IBM or IBM-compatible type, which has been provided with application software to constitute a reception system (RS) 400.

US 7,072,849 B1

5

As seen in FIG. 1, interactive network 10 uses a layered structure that includes an information layer 100, a switch/file server layer 200, and cache/concentrator layer 300 as well as reception layer 401. This structure maintains active application databases and delivers requested parts of the databases on demand to the plurality of RS 400's, shown in FIG. 2. As seen in FIG. 2, cache/concentrator layer 300 includes a plurality of cache/concentrator units 302, each of which serve a plurality of RS 400 units over lines 301. Additionally, switch/file server layer 200 is seen to include a server unit 205 connected to multiple cache/concentrator units 302 over lines 201. Still further, server unit 205 is seen to be connected to information layer 100 and its various elements, which act as means for producing, supplying and maintaining the network databases and other information necessary to support network 10. Continuing, switch/filer layer 200 is also seen to include gateway systems 210 connected to server 205. Gateways 210 couple layer 200 to other sources of information and data; e.g., other computer systems. As will be appreciated by those skilled in the art, layer 200, like layers 401 and 300, could also include multiple servers, gateways and information layers in the event even larger numbers of users were sought to be served.

Continuing with reference to FIG. 2, in preferred form, each RS 400 is seen to include a personal computer 405 having a CPU 410 including a microprocessor (as for example, one of the types made by INTEL Corporation in its X'86 family of microprocessors), companion RAM and ROM memory and other associated elements, such as monitor 412 with screen 414 and a keyboard 424. Further, personal computer 405 may also include one or two floppy disk drives 416 for receiving diskettes 426 containing application software used to support the interactive service and facilitate the interactive sessions with network 10. Additionally, personal computer 405 would include operating systems software; e.g., MS-DOS, supplied on diskettes 428 suitable for the personal computer being used. Personal computer 405 still further may also include a hard-disk drive 420 for storing the application software and operating system software which may be transferred from diskettes 426 and 428 respectfully.

Once so configured, each RS 400 provides: a common interface to other elements of interactive computer network 10; a common environment for application processing; and a common protocol for user-application conversation which is independent of the personal computer brand used. RS 400 thus constitutes a universal terminal for which only one version of all applications on network 10 need be prepared, thereby rendering the applications interpretable by a variety of brands of personal computers.

RS 400 formulated in this fashion is capable of communication with the host system to receive information containing either of two types of data, namely objects and messages. Objects have a uniform, self-defining format known to RS 400, and include data types, such as interpretable programs and presentation data for display at monitor screen 414 of the user's personal computer 405. Applications presented at RS 400 are partitioned into objects which represent the minimal units available from the higher levels of interactive network 10 or RS 400. In this arrangement, each application partition typically represents one screen or a partial screen of information, including fields filled with data used in transactions with network 10. Each such screen, commonly called a page, is represented by its parts and is described in a page template object, discussed below.

Applications, having been partitioned into minimal units, are available from higher elements of network 10 or RS 400,

6

and are retrieved on demand by RS 400 for interpretive execution. Thus, not all partitions of a partitioned application need be resident at RS 400 to process a selected partition, thereby raising the storage efficiency of the user's RS 400 and minimizing response time. Each application partition is an independent, self-contained unit and can operate correctly by itself. Each partition may refer to other partitions either statically or dynamically. Static references are built into the partitioned application, while dynamic references are created from the execution of program logic using a set of parameters, such as user demographics or locale. Partitions may be chosen as part of the RS processing in response to user created events, or by selecting a key word of the partitioned application (e.g., "JUMP" or "INDEX," discussed below), which provides random access to all services represented by partitioned applications having key words.

Objects provide a means of packaging and distributing partitioned applications. As noted, objects make up one or more partitioned applications, and are retrieved on demand by a user's RS 400 for interpretive execution and selective storage. All objects are interpreted by RS 400, thereby enabling applications to be developed independently of the personal computer brand used.

Objects may be nested within one another or referenced by an object identifier (object-id) from within their data structure. References to objects permit the size of objects to be minimized. Further, the time required to display a page is minimized when referenced objects are stored locally at RS 400 (which storage is determined by prior usage meeting certain retention criteria), or have been pre-fetched, or in fact, are already used for the current page.

Objects carry application program instructions and/or information for display at monitor screen 414 of RS 400. Application program objects, called pre-processors and post-processors, set up the environment for the user's interaction with network 10 and respond to events created when the user inputs information at keyboard 424 of RS 400. Such events typically trigger a program object to be processed, causing one of the following: sending of transactional information to the coapplications in one layer of the network 10; the receiving of information for use in programs or for presentation in application-dependent fields on monitor screen 414; or the requesting of a new objects to be processed by RS 400. Such objects may be part of the same application or a completely new application.

The RS 400 supports a protocol by which the user and the partitioned applications communicate. All partitioned applications are designed knowing that this protocol will be supported in RS 400. Hence, replication of the protocol in each partitioned application is avoided, thereby minimizing the size of the partitioned application.

RS 400 includes a means to communicate with network 10 to retrieve objects in response to events occurring at RS 400 and to send and receive messages.

RS 400 includes a means to selectively store objects according to a predetermined storage criterion, thus enabling frequently used objects to be stored locally at the RS, and causing infrequently used objects to forfeit their local storage location. The currency of objects stored locally at the RS 400 is verified before use according to the object's storage control parameters and the storage criterion in use for version checking.

Selective storage tailors the contents of the RS 400 memory to contain objects representing all or significant parts of partitioned applications favored by the user.

US 7,072,849 B1

7

Because selective storage of objects is local, response time is reduced for those partitioned applications that the user accesses most frequently.

Since much of the application processing formerly done by a host computer in previously known time-sharing networks is now performed at the user's RS 400, the higher elements of network 10, particularly layer 200, have as their primary functions the routing of messages, serving of objects, and line concentration. The narrowed functional load of the higher network elements permits many more users to be serviced within the same bounds of computer power and I/O capability of conventional host-centered architectures.

Network 10 provides information on a wide variety of topics, including, but not limited to news, industry, financial needs, hobbies and cultural interests. Network 10 thus eliminates the need to consult multiple information sources, giving users an efficient and timesaving overview of subjects that interest them.

The transactional features of interactive network 10 saves the user time, money, and frustration by reducing time spent traveling, standing in line, and communicating with sales personnel. The user may, through RS 400, bank, send and receive messages, review advertising provided in accordance with the method of the present invention, place orders for merchandise, and perform other transactions.

In preferred form, network 10 provides information, advertising and transaction processing services for a large number of users simultaneously accessing the network via the public switched telephone network (PSTN), broadcast, and/or other media with their RS 400 units. Services available to the user include display of information such as movie reviews, the latest news, airlines reservations, the purchase of items such as retail merchandise and groceries, and quotes and buy/sell orders for stocks and bonds. Network 10 provides an environment in which a user, via RS 400 establishes a session with the network and accesses a large number of services. These services are specifically constructed applications which as noted are partitioned so they may be distributed without undue transmission time, and may be processed and selectively stored on a user's RS 400 unit.

#### System Configuration

As shown in FIG. 1, interactive computer network 10 includes four layers: information layer 100, switch and file server layer 200, concentrator layer 300, and reception layer 401.

Information layer 100 handles: (1) the production, storage and dissemination of data and (2) the collection and off-line processing of such data from each RS session with the network 10 so as to permit the targeting of information and advertising to be presented to users and for traditional business support.

Switch and file server layer 200 and cache/concentrator layer 300 together constitute a delivery system 20 which delivers requested data to the RS 400's of reception layer 401 and routes data entered by the user or collected at RS 400's to the proper application in network 10. With reference to FIG. 2, the information used in a RS 400 either resides locally at the RS 400, or is available on demand from the cache/concentrator 300 or the file server 205, via the gateway 210, which may be coupled to external providers, or is available from information layer 100.

There are two types of information in the network 10 which are utilized by the RS 400: objects and messages.

8

Objects include the information requested and utilized by the RS 400 to permit a user to select specific parts of applications, control the flow of information relating to the applications, and to supply information to the network. Objects are self-describing structures organized in accordance with a specific data object architecture, described below. Objects are used to package presentation data and program instructions required to support the partitioned applications and advertising presented at a RS 400. Objects are distributed on demand throughout interactive network 10. Objects may contain: control information; program instructions to set up an application processing environment and to process user or network created events; information about what is to be displayed and how it is to be displayed; references to programs to be interpretively executed; and references to other objects, which may be called based upon certain conditions or the occurrence of certain events at the user's personal computer, resulting in the selection and retrieval of other partitioned applications packaged as objects.

Messages are information provided by the user or the network and are used in fields defined within the constructs of an object, and are seen on the user's RS monitor 412, or are used for data processing at RS 400. Additionally, and as more fully described hereafter, messages are the primary means for communication within and without the network. The format of messages is application dependent. If the message is input by the user, it is formatted by the partitioned application currently being processed on RS 400. Likewise, and with reference to FIG. 2, if the data are provided from a co-application database residing in delivery system 20, or accessed via gateway 210 or high function system 110 within the information layer 100, the partitioned application currently being processed on RS 400 causes the message data to be displayed in fields on the user's display monitor as defined by the particular partitioned application.

All active objects reside in file server 205. Inactive objects or objects in preparation reside in producer system 120. Objects recently introduced into delivery system 20 from the producer system 120 will be available from file server 205, but, may not be available on cache/concentrator 302 to which the user's RS 400 has dialed. If such objects are requested by the RS 400, the cache/concentrator 302 automatically requests the object from file server 205. The requested object is routed back to the requesting cache/concentrator 302, which automatically routes it to the communications line on which the request was originally made, from which it is received by the RS 400.

The RS 400 is the point of application session control because it has the ability to select and randomly access objects representing all or part of partitioned applications and their data. RS 400 processes objects according to information contained therein and events created by the user on personal computer 405.

Applications on network 10 act in concert with the distributed partitioned applications running on RS 400. Partitioned applications constructed as groups of objects and are distributed on demand to a user's RS 400. An application partition represents the minimum amount of information and program logic needed to present a page or window, i.e. portion of a page presented to the user, perform transactions with the interactive network 10, and perform traditional data processing operations, as required, including selecting another partitioned application to be processed upon a user generated completion event for the current partitioned application.

US 7,072,849 B1

9

Objects representing all or part of partitioned applications may be stored in a user's RS 400 if the objects meet certain criteria, such as being non-volatile, non-critical to network integrity, or if they are critical to ensuring reasonable response time. Such objects are either provided on diskettes 426 together with RS 400 system software used during the installation procedure or they are automatically requested by RS 400 when the user makes selections requiring objects not present in RS 400. In the latter case, RS 400 requests from cache/concentrator layer 300 only the objects necessary to execute the desired partitioned application.

Reception system application software 426 in preferred form is provided for IBM and IBM-compatible brands of personal computers 405, and all partitioned applications are constructed according to a single architecture which each such RS 400 supports. With reference to FIG. 2, to access network 10, a user preferably has a personal computer 405 with at least 512K RAM and a single disk drive 416. The user typically accesses network 10 using a 1,200 or 2,400 bps modem (not shown). To initiate a session with network 10, objects representing the logon application are retrieved from the user's personal diskette, including the R.S. application software, which was previously set up during standard installation and enrollment procedures with network 10. Once communication between RS 400 and cache/concentrator layer 300 has been established, the user begins a standard logon procedure by inputting a personal entry code. Once the logon procedure is complete, the user can begin to access various desired services (i.e., partitioned applications) which provide display of requested information and/or transaction operations.

#### Applications and Pages

Applications, i.e. information events, are composed of a sequence of one or more pages opened at screen 414 of monitor 412. This is better seen with reference to FIGS. 3a and 3b where a page 255 is illustrated as might appear at screen 414 of monitor 412. With reference to FIG. 3a, each page 255 is formatted with a service interface having page partitions 250, 260, 280, and 290 (not to be confused with application partitions). Window page partitions 275, well known in the art, are also available and are opened and closed conditionally on page 255 upon the occurrence of an event specified in the application being run. Each page partition 250, 260, 280 and 290 and window 275 is made up of a page element which defines the content of the partition or window.

Each page 255 includes: a header page partition 250, which has a page element associated with it and which typically conveys information on the page's topic or sponsor; one or more body page partitions 260 and window page partitions 275, each of which is associated with a page element which as noted gives the informational and transactional content of the page. For example, a page element may contain presentation data selected as a menu option in the previous page, and/or may contain prompts to which a user responds in pre-defined fields to execute transactions. As illustrated in FIG. 3b, the page element associated with body page partition 260—includes display fields 270, 271, 272. A window page partition 275 seen in FIG. 3a represents the same informational and transactional capability as a body partition, except greater flexibility is provided for its location and size.

Continuing with reference to FIG. 3a, in accordance with the invention, advertising 280 is provided over network 10, like page elements, also includes information for display on

10

page 255, and may be included in any partition of a page. Advertising 280 is presented to the user on an individualized basis from queues of advertising object identifications (ids) that are constructed off-line by business system 130, and sent to file server 205 where they are accessible to each RS 400.

Individualized queues of advertising object ids are constructed based upon data collected on the partitioned applications that were accessed by a user, and upon events the user generated in response to applications. The data are collected and reported by RS 400 to a data collection co-application in file server 205 for later transmission to business system 130. In addition to application access and use characteristics, a variety of other parameters, such as user demographics or postal ZIP code, may be used as targeting criteria. From such data, queues of advertising object ids are constructed that are targeted to either individual users or to sets of users who fall into certain groups according to such parameters. Stated otherwise, the advertising presented is individualized to the respective users based on characterizations of the respective users as defined by the interaction history with the service and such other information as user demographics and locale. As will be appreciated by those skilled in the art, conventional marketing analysis techniques can be employed to establish the user characterizations based on the collected application usage data above noted and other information.

Also with reference to FIG. 3b, the service interface is seen to include a command region 285 which enables the user to interact with the network RS 400 and other elements of network 10, so as to cause such operations as navigating from page to page, performing a transaction, or obtaining more information about other applications. As shown in FIG. 3b, interface region 285 includes a command bar 290—having a number of commands 291–298 which the user can execute. The functions of commands 291–298 are discussed in greater detail below.

#### Network Objects

As noted above, in conventional time-sharing computer networks, the data and program instructions necessary to support user sessions are maintained at a central host computer. However, that approach has been found to create processing bottlenecks as greater numbers of users are connected to the network; bottlenecks which require increases in processing power and complexity; e.g., multiple hosts of greater computing capability, if the network is to meet demand. Further, such bottlenecks have been found to also slow response time as more users are connected to the network and seek to have their requests for data processing answered.

The consequences of the host processing bottlenecking is to either compel capital expenditures to expand host processing capability, or accept longer response times; i.e., a slower network, and risk user dissatisfaction.

However, even in the case where additional computing power is added, and where response time is allowed to increase, eventually the host becomes user saturated as more and more users are sought to be served by the network. The network described above, however, is designed to alleviate the effects of host-centered limitations, and extend the network saturation point. This objective is achieved by reducing the demand on the host for processing resources by structuring the network so that the higher network levels act primarily to maintain and supply data and programs to the

US 7,072,849 B1

11

lower levels of the network, particularly RS 400, which acts to manage and sustain the user screen displays.

More particularly, the described network features procedures for parsing the network data and program instructions required to support the interactive user sessions into packets, referred to as objects, and distributing them into the network where they can be processed at lower levels, particularly, reception system 400.

In accordance with the method of the present invention, the screens presented at the user's monitor are each divided into addressable partitions shown in FIG. 3a, and the display text and graphics necessary to make up the partitions, as well as the program instructions and control data necessary to deliver and sustain the screens and partitions, are formulated from pre-created objects. Further, the objects are structured in accordance with an architecture that permits the displayed data to be relocatable on the screen, and to be reusable to make up other screens and other sessions, either as pre-created and stored sessions or interactive sessions, dynamically created in response to the user's requests.

As shown in FIG. 4c, the network objects are organized as a family of objects each of which perform a specific function in support of the interactive session. More particularly, in accordance with the preferred form of the invention, the network object family is seen to include 6 members: page format objects 502, page element objects 504, window objects 506, program objects 508, advertisement objects 510 and page template objects 500.

Within this family, page format objects 502 are designed to define the partitioning 250 to 290 of the monitor screen shown in FIG. 3a. The page format objects 502 provide a means for pre-defining screen partitions and for ensuring a uniform look to the page presented on the reception system monitor. They provide the origin; i.e., drawing points, and dimensions of each page partition and different values for presentation commands such as palette and background color.

Page format objects 502 are referenced whenever non-window data is to be displayed and as noted ensure a consistent presentation of the page. In addition, page format objects 502 assures proper tessellation or "tiling" of the displayed partitions.

Page element objects 504, on the other hand, are structured to contain the display data; i.e., text and graphic, to be displayed which is mapped within screen partitions 250 to 290, and to further provide the associated control data and programs. More specifically, the display data is described within the object as NAPLPS data, and includes, PDI, ASCII, Incremental Point and other display encoding schemes. Page element objects also control the functionality within the screen partition by means of field definition segments 516 and program call segments 532, as further described in connection with the description of such segments hereafter. Page element objects 504 are relocatable and may be reused by many pages. To enable the displayable data to be relocated, display data must be created by producers in the NAPLPS relative mode.

Continuing with reference to FIG. 4c, window objects 506 include the display and control data necessary to support window partitions 275 best seen in FIG. 3a. Windows contain display data which overlay the base page and control data which supersede the base page control data for the underlying screen during the duration of the window. Window objects 506 contain data which is to be displayed or otherwise presented to the viewer which is relatively independent from the rest of the page. Display data within windows overlay the base page until the window is closed.

12

Logic associated with the window supersedes base page logic for the duration of the window. When a window is opened, the bit map of the area covered by window is saved and most logic functions for the overlaid page are deactivated. When the window is closed, the saved bit map is swapped onto the screen, the logic functions associated with the window are disabled, and prior logic functions are reactivated.

Windows are opened by user or program control. They do not form part of the base page. Windows would typically be opened as a result of the completion of events specified in program call segments 532.

Window objects 506 are very similar in structure to page element objects 504. The critical difference is that window objects 506 specify their own size and absolute screen location by means of a partition definition segment 528.

Program objects 508 contain program instructions written in a high-level language called TRINTEX Basic Object Language, i.e., TBOL, described in greater detail hereafter, which may be executed on RS 400 to support the application. More particularly, program objects 508 include interpretable program code, executable machine code and parameters to be acted upon in conjunction with the presentation of text and graphics to the reception system monitors.

Program objects 508 may be called for execution by means of program call segments 532, which specify when a program is to be executed (event), what program to execute (program pointer), and how programs should run (parameters).

Programs are treated as objects to conform to the open-ended design philosophy of the data object architecture (DOA), allowing the dissemination of newly developed programs to be easily and economically performed. As noted above, it is desirable to have as many of these program objects staged for execution at or as close to RS 400 as possible.

Still further, in accordance with the method of the present invention, advertising objects 510 include the text and graphics that may be presented at ad partition 280 presented on the monitor screen as shown in FIG. 3b.

Finally, the object family includes page template objects 500. Page template objects 500 are designed to define the components of the full screen presented to the viewer. Particularly, page template objects 500 include the entry point to a screen, the name of the page format objects which specify the various partitions a screen will have and the page element object that contain the display data and partitioning parameters for the page.

Additionally, page template object 500 includes the specific program calls required to execute the screens associated with the application being presented to the user, and may serve as the means for the user to selectively move through; i.e., navigate the pages of interest which are associated with various applications. Thus, in effect, page template objects 500 constitute the "recipe" for making up the collection of text and graphic information required to make the screens to be presented to the user.

Also in accordance with the invention, object 500 to 510 shown in FIG. 4c are themselves made up of further sub-blocks of information that may be selectively collected to define the objects and resulting pages that ultimately constitute the application presented to the user in an interactive text and graphic session.

More specifically and as shown schematically in FIG. 4a, objects 500 to 510 are predefined, variable length records consisting of a fixed length header 551 and one or more

## US 7,072,849 B1

13

self-defining record segments **552** a list of which is presented in FIG. **4c** as segment types **512** to **540**.

In accordance with this design, and as shown in FIG. **4b**, object header **551** in preferred form is 18 bytes in length and contains a prescribed sequence of information which provides data regarding the object's identification, its anticipated use, association to other objects, its length and its version and currency.

More particularly, each of the 18 bytes of object header **551** are conventional hexadecimal, 8 bit bytes and are arranged in a fixed pattern to facilitate interpretation by network **10**. Particularly, and as shown in FIG. **4b**, the first byte of header **551**; i.e., byte **1**, identifies the length of the object ID in hexadecimal. The next six bytes; i.e., bytes **2** to **7**, are allocated for identifying access control to the object so as to allow creation of closed user groups to whom the object(s) is to be provided. As will be appreciated by those skilled in the art, the ability to earmark objects in anticipation of user requests enables the network anticipate requests and pre-collect objects from large numbers of them maintained to render the network more efficient and reduce response time. The following 4 bytes of header **551**; bytes **8** to **11**, are used to identify the set of objects to which the subject object belongs. In this regard, it will be appreciated that, again, for speed of access and efficiency of selection, the objects are arranged in groups or sets which are likely to be presented to user sequentially in presenting the page sets; i.e., screens that go to make up a session.

Following identification of the object set, the next byte in header **551**; i.e., byte **12**, gives the location of the subject object in the set. As will be appreciated here also the identification is provided to facilitate ease of object location and access among the many thousands of objects that are maintained to, thereby, render their selection and presentation more efficient and speedy.

Thereafter, the following bytes of header **551**; i.e., byte **13**, designates the object type; e.g., page format, page template, page element, etc. Following identification of the object type, two bytes; i.e., bytes **14**, **15**, are allocated to define the length of the object, which may be of whatever length is necessary to supply the data necessary, and thereby provides great flexibility for creation of the screens. Thereafter, a single byte; i.e., byte **16**, is allocated to identify the storage characteristic for the object; i.e., the criterion which establishes at what level in network **10** the object will be stored, and the basis upon which it will be updated. At least a portion of this byte; i.e., the higher order nibble (first 4 bits reading from left to right) is associated with the last byte; i.e., byte **18**, in the header which identifies the version of the object, a control used in determining how often in a predetermined period of time the object will be updated by the network.

Following storage characteristic byte **16**, header **551** includes a byte; i.e., **17**, which identifies the number of objects in the set to which the subject object belongs. Finally, and as noted above, header **551** includes a byte; i.e., **18**, which identifies the version of the object. Particularly the object version is a number to establish the control for the update of the object that are resident at RS **400**.

As shown in FIG. **4a**, and as noted above, in addition to header **551**, the object includes one more of the various segment types shown in FIG. **4c**.

Segments **512** to **540** are the basic building blocks of the objects. And, as in the case of the object, the segments are also self-defining. As will be appreciated by those skilled in the art, by making the segments self-defining, changes in the

14

objects and their use in the network can be made without changing pre-existing objects.

As in the case of objects, the segments have also been provided with a specific structure. Particularly, and as shown in FIG. **4a**, segments **552** consists of a designation of segment type **553**, identification of segment length **554**, followed by the information necessary to implement the segment and its associated object **555**; e.g., either, control data, display data or program code.

In this structure, segment type **553** is identified with a one-byte hexadecimal code which describes the general function of the segment. Thereafter, segment length **554** is identified as a fixed two-byte long field which carries the segment length as a hexadecimal number in INTEL format; i.e., least significant byte first. Finally, data within segments may be identified either by position or keyword, depending on the specific requirements of the segment.

The specific structure for the objects and segments in shown in FIG. **4c** and is described below. In that description the following notation convention is used:

< >—mandatory item

( )—optional item

. . . —item may be repeated

|item| |item|

< > ( )—items in a column indicate either/or

|item| |item|

The structure for objects is:

PAGE TEMPLATE OBJECT,

[<header> (compression descriptor) <page format call> (page element call) . . . (program call) . . . (page element selector) (system table call) . . . external reference) (keyword/navigation) . . . ];

As noted above, page format objects **502** are designed to define the partitioning **250** to **290** of monitor screen **414** shown in FIG. **3a**.

PAGE FORMAT OBJECT,

[<header> (compression descriptor) (page defaults) <partition definition>];

PAGE ELEMENT OBJECT,

[<header> (compression descriptor) (presentation data) . . . (program call) . . . (custom cursor) . . . (custom text) . . . (field definition) . . . (field-level program call) . . . (custom cursor type 2) . . . (custom graphic) . . . (field definition type 2) . . . (array definition) . . . (inventory control)];

Page element objects, as explained, are structured to contain the display data; i.e., text and graphics, to be presented at screen partitions **250** to **290**.

WINDOW OBJECT,

[<header> (compression description) <partition definition> (page element call) (presentation data) . . . (program call) . . . (custom cursor) . . . (custom text) . . . (custom cursor type 2) . . . (custom graphic) . . . (field definition) . . . (field level program call) . . . (field definition type 2) . . . (array definition) . . . (inventory control)];

As noted, window objects include display and control data necessary to support window partition at screen **414**.

PROGRAM OBJECTS,

[<header> (compression descriptor) <program data> . . . ].

Program objects, on the other hand, contain program instructions written in higher-level language which may be executed at RS **400** to support the application.

US 7,072,849 B1

15

## ADVERTISEMENT OBJECT,

[<header> (compression descriptor) (presentation data) . . . (program call) . . . (custom cursor) . . . (custom text) . . . (field definition) . . . (field-level program call) . . . (custom cursor type 2) . . . (custom graphic) . . . (field definition type 2) . . . (array definition) . . . (inventory control)];

In accordance with the invention, and as can be seen, advertisement objects are substantially the same as page element objects, with the difference being that, as their name implies, their subject matter is selected to concern advertising.

Continuing, the structure for the object segments follows from the above description, and is as described more fully in parent application Ser. No. 388,156 now issued as U.S. Pat. No. 5,347,632, the contents of which patent are incorporated herein by reference.

## Network Messages

In addition to the network objects, and the display data, control data, and the program instructions they contain as previously described, network 10 also exchanges information regarding the support of user sessions and the maintenance of the network as "messenger". Specifically, messages typically relate to the exchange of information associated with initial logon of a reception system 400 to network 10, dialogue between RS 400 and other elements and communications by the other network elements amongst themselves.

To facilitate message exchange internally, and through gateway 210 to entities externally to network 10, a protocol termed the "Data Interchange Architecture" (DIA) is used to support the transport and interpretation of information. More particularly, DIA enables: communications between RS 400 units, separation of functions between network layers 100, 200, 300 and 401; consistent parsing of data; an "open" architecture for network 10; downward compatibility within the network; compatibility with standard industry protocols such as the IBM System Network Architecture; Open Systems Interconnections standard; support of network utility sessions; and standardization of common network and application return codes.

Thus DIA binds the various components of network 10 into a coherent entity by providing a common data stream for communications management purposes. DIA provides the ability to route messages between applications based in IBM System Network Architecture (SNA), (well known in the art, and more fully described in *Data and Computer Communications*, by W. Stallings, Chapter 12, McMillian Publishing, Inc. (1985)) and non-SNA reception system applications; e.g. home computer applications. Further, DIA provides common data structure between applications run at RS 400 units and applications that may be run on external computer networks; e.g. Dow Jones Services, accessed through gateway 210. As well, DIA provides support for utility sessions between backbone applications run within network 10. A more detailed description of network messaging is provided in above noted U.S. Pat. No. 5,347,632, the content of which is incorporated herein by reference.

## Object Language

In accordance with the design of network 10, in order to enable the manipulation of the network objects, the application programs necessary to support the interactive text/graphic sessions are written in a high-level language referred

16

to as "TBOL", (TRINTEX Basic Object Language, "TRINTEX" being the former company name of one of the assignees of this invention). TBOL is specifically adapted for writing the application programs so that the programs may be compiled into a compact data stream that can be interpreted by the application software operating in the user personal computer, the application software being designed to establish the network Reception System 400 previously noted and described in more detail hereafter.

The Reception System application software supports an interactive text/graphics sessions by managing objects. As explained above, objects specify the format and provide the content; i.e., the text and graphics, displayed on the user's screen so as to make up the pages that constitute the application. As also explained, pages are divided into separate areas called "partitions" by certain objects, while certain other objects describe windows which can be opened on the pages. Further, still other objects contain TBOL application programs which facilitate the data processing necessary to present the pages and their associated text and graphics.

As noted, the object architecture allows logical events to be specified in the object definitions. An example of a logical event is the completion of data entry on a screen; i.e., an application page. Logical events are mapped to physical events such as the user pressing the <ENTER> key on the keyboard. Other logical events might be the initial display of a screen page or the completion of data entry in a field. Logical events specified in page and window object definitions can be associated with the call of TBOL program objects.

RS 400 is aware of the occurrence of all physical events during the interactive text/graphic sessions. When a physical event such as depression of the forward <TAB> key corresponds to a logical event such as completion of data entry in a field, the appropriate TBOL program is executed if specified in the object definition. Accordingly, the TBOL programs can be thought of as routines which are given control to perform initialization and post-processing application logic associated with the fields, partitions and screens at the text/graphic sessions.

RS 400 run time environment uses the TBOL programs and their high-level key-word commands called verbs to provide all the system services needed to support a text/graphic session, particularly, display management, user input, local and remote data access.

TBOL programs have a structure that includes three sections: a header section in which the program name is specified; a data section in which the data structure the program will use are defined; and a code section in which the program logic is provided composed of one or more procedures. More specifically, the code section procedures are composed of procedure statements, each of which begins with a TBOL key word called a verb.

The name of a procedure can also be used as the verb in a procedure statement exactly as if it were a TBOL key-word verb. This feature enables a programmer to extend the language vocabulary to include customized application-oriented verb commands.

Continuing, TBOL programs have a program syntax that includes a series of "identifiers" which are the names and labels assigned to programs, procedures, and data structures.

An identifier may be up to 31 characters long; contain only uppercase or lowercase letters A through Z, digits 0 through 9, and/or the special character underscore (\_); and must begin with a letter. Included among the system identifiers are: "header section identifiers" used in the header section for the program name; "data section identifiers" used

US 7,072,849 B1

17

in the data section for data structure names, field names and array names; and finally, "code section identifiers" used in the code section for identification of procedure names and statement labels. A more detailed description of TBOL is provided in parent application Ser. No. 388,156 now issued as U.S. Pat. No. 5,347,632, the contents of which patent are incorporated herein by reference.

#### Reception System Operation

RS 400 of computer system network 10 uses software called native code modules (described below) to enable the user to select options and functions presented on the monitor screen 414 of personal computer 405, to execute partitioned applications and to process user created events, enabling the partitioned application to interact with network 10. Through this interaction, the user is able to input data into fields provided as part of the display, or may individually select choices causing a standard or personalized page to be built (as explained below) for display on the monitor of personal computer 405. Such inputs will cause RS 400 to interpret events and trigger pre-processors or post-processors, retrieve specified objects, communicate with system components, control user options, cause the display of advertisements on a page, open or close window partitions to provide additional navigation possibilities, and collect and report data about events, including certain types of objects processed. For example, the user may select a particular option, such as opening or closing window partition 275, which is present on the monitor and follow the selection with a completion key stroke, such as ENTER. When the completion keystroke is made, the selection is translated into a logical event that triggers the execution of a post-processor, (i.e., a partitioned application program object) to process the contents of the field.

Functions supporting the user-partitioned application interface can be performed using the command bar 290, or its equivalent using pull down windows or an overlapping cascade of windows. These functions can be implemented as part of the RS native functions or can be treated as another partition(s) defined for every page for which an appropriate set of supporting objects exist and remain resident at RS 400. If the functions are part of RS 400, they can be altered or extended by verbs defined in the RS virtual machine that permit the execution of program objects to be triggered when certain functions are called, providing maximum flexibility.

To explain the functions the use of a command bar is assumed. Command bar 290 is shown in FIGS. 3a and 3b and includes a NEXT command 291, a BACK command 292, a PATH command 293, a MENU command 294, an ACTION command 295, a JUMP command 296, a HELP command 297, and an EXIT command 298.

NEXT command 291 causes the next page in the current page set to be built. If the last page of a page set has already been reached, NEXT command 291 is disabled by RS 400, avoiding the presentation of an invalid option.

BACK command 292 causes the previous page of the current page set to be built. If the present page is the first in the page set, BACK command 292 is disabled, since it is not a valid option.

A filter program can be attached to both the NEXT or BACK functions to modify their implicit sequential nature based upon the value of the occurrence in the object set id.

PATH command 293 causes the next page to be built and displayed from a list of pages that the user has entered, starting from the first entry for every new session.

18

MENU command 294 causes the page presenting the previous set of choices to be rebuilt.

ACTION command 295 initiates an application dependent operation such as causing a new application partition to be interpreted, a window partition 275 to be opened and enables the user to input any information required which may result in a transaction or selection of another window or page.

JUMP command 296 causes window partition 275 to be opened, allowing the user to input a keyword or to specify one from an index that may be selected for display.

HELP command 297 causes a new application partition to be interpreted such as a HELP window pertaining to where the cursor is positioned to be displayed in order to assist the user regarding the present page, a particular partition, or a field in a page element.

EXIT command 298 causes a LOGOFF page template object (PTO) to be built, and a page logoff sequence to be presented at RS 400 monitor screen 414.

#### Navigation Interface

Continuing, as a further feature, network 10 includes an improved procedure for searching and retrieving applications from the store of applications distributed throughout network 10; e.g., server 205, cache/concentrator 302 and RS 400. More specifically, the procedure features use of pre-created search tables which represent subsets of the information on the network arranged with reference to the page template objects (PTO) and object-ids of the available applications so that in accordance with the procedure, the relevant tables and associated objects can be provided to and searched at the requesting RS 400 without need to search the entire store of applications on the network. As will be appreciated, this reduces the demand on the server 205 for locating and retrieving applications for display at monitor 412.

In conventional time-sharing networks that support large conventional databases, the host receives user requests for data records; locates them; and transmits them back to the users. Accordingly, the host is obliged to undertake the data processing necessary to isolate and supply the requested information. And, as noted earlier, where large numbers of users are to be served, the many user requests can bottleneck at the host, taxing resources and leading to response slowdown.

Further, users have experienced difficulty in searching data bases maintained on conventional time-sharing networks. For example, difficulties have resulted from the complex and varied way previously known database suppliers have organized and presented their information. Particularly, some database providers require searching be done only in selected fields of the data base, thus requiring the user to be fully familiar with the record structure. Others have organized their databases on hierarchial structures which require the user understand the way the records are grouped. Still further, yet other database suppliers rely upon keyword indices to facilitate searching of their records, thus requiring the user to be knowledgeable regarding the particular keywords used by the database provider.

Network 10, however, is designed to avoid such difficulties. In the preferred embodiment, the network includes procedures for creating preliminary searches which represent subsets of the network applications users are believed likely to investigate. Particularly, in accordance with these procedures, for the active applications available on network 10, a library of tables is prepared, and maintained within

US 7,072,849 B1

19

each of which a plurality of so called "keywords" are provided that are correlated with page template objects and object-ids of the entry screen (typically the first screen) for the respective application. In the preferred embodiment, approximately 1,000 tables are used, each having approximately 10 to 20 keywords arranged in alphabetical order to abstract the applications on the network. Further, the object-id for each table is associated with a code in the form of a character string mnemonic which is arranged in a set of alphabetically sequenced mnemonics termed the sequence set so that on entry of a character string at an RS 400, the object-id for the relevant keyword table can be obtained from the sequence set. Once the table object-id is identified, the keyword table corresponding to the desired subset of the objects and associated applications can then be obtained from network 10. Subsequently the table can be presented to the user's RS 400, where the RS 400 can provide the data processing required to present the potentially relevant keywords, objects and associated applications to the user for further review and determination as to whether more searching is required. As will be appreciated, this procedure reduces demand on server 205 and thereby permits it to be less complex and costly, and further, reduces the likelihood of host overtaxing that may cause network response slowdown.

As a further feature of this procedure, the library of keywords and their associated PTOs and objects may be generated by a plurality of operations which appear at the user's screen as different search techniques. This permits the user to select a search technique he is most comfortable with, thus expediting his inquiry.

More particularly, the user is allowed to invoke the procedure by calling up a variety of operations. The various operations have different names and seemingly present different search strategies. Specifically, the user may invoke the procedure by initiating a "Jump" command at RS 400. Thereafter, in connection with the Jump operation, the user, when prompted, may enter a word of the user's choosing at monitor screen 414 relating to the matter he is interested in locating; i.e., a subject matter search of the network applications. Additionally, the users may invoke the procedure by alternatively calling up an operation termed "Index" with selection of the Index command. When selected, the Index command presents the user with an alphabetical listing of keywords from the tables noted above which the user can select from; i.e., an alphabetical search of the network applications. Further, the user may evoke the procedure by initiating an operation termed "Guide." By selecting the Guide command, the user is provided with a series of graphic displays that presents a physical description of the network applications; e.g., department floor plan for a store the user may be electronically shopping in. Still further, the user may invoke the procedures by initiating an operation termed "Directory." By selecting the Directory command, the user is presented with the applications available on the network as a series of hierarchical menus which present the content of the network information in commonly understood categories. Finally, the user may invoke the procedure by selecting the "Path" command, which accesses a list of keywords the user has previously selected; i.e., a personally tailored form of the Index command described above. As described hereafter, Path further includes a Viewpath operation which permits the user to visually access and manage the Path list of keywords. In preferred form, where the user has not selected a list of personalized keywords, a default set

20

is provided which includes a predetermined list and associated applications deemed by network 10 as likely to be of interest to the user.

This ability to convert these apparently different search strategies in a single procedure for accessing pre-created library tables is accomplished by translating the procedural elements of the different search techniques into a single set of procedures that will produce a mnemonic; i.e., code word, which can first be searched at the sequence set, described above to identify the object-id for the appropriate library table and, thereafter, enable access of the appropriate table to permit selection of the desired keyword and associated PTO and object-ids. That is to say, the reception system native code simply relates the user-entered character string, alphabetical range, category, or list item of respectively, "Jump", "Index", "Directory", or "Path" to the table codes through the sequence set, so that the appropriate table can be provided to the reception system and application keyword selected. Thus, while the search techniques may appear different to the user, and in fact accommodate the user's preferences and sophistication level, they nonetheless invoke the same efficient procedure of relying upon pre-created searches which identify related application PTOs and object-ids so that the table and objects may be collected and presented at the user's RS 400 where they can be processed, thereby relieving server 205.

In preferred form, however, in order to enhance presentation speed the Guide operation is specially configured. Rather than relating the keyword mnemonic to a sequence set to identify the table object-id and range of keywords corresponding to the entry PTO and associated object-ids, the Guide operation presents a series of overlapping windows that physically describe the "store" in which shopping is being conducted or the "building" from which information is being provided. The successive windows increase in degree of detail, with the final window presenting a listing of relevant keywords. Further, the PTO and object-ids for the application entry screen are directly related to the graphic presentation of the keywords. This eliminates the need to provide variable fields in the windows for each of the keywords and enables the entry screen to be correlated directly with the window graphic. As will be appreciated, this reduces the number of objects that would otherwise be required to be staged at RS 400 to support pretention of the keyword listing at monitor screen 414, and thus speeds network response.

A more detailed understanding of the procedure may be had upon a reading of the following description and review of accompanying FIGS. 2, 3a and particularly FIG. 11 which presents a flow diagram for the Jump sequence of the search procedure.

To select a particular partitioned application from among thousands of such applications residing either at the RS 400 or within delivery system 20, network 10 avoids the need for a user to know or understand, prior to a search, the organization of such partitioned applications and the query techniques necessary to access them. This is accomplished using a collection of related commands, as described below.

The Jump command 296 as seen in FIG. 3a, can be selected, by the user from command bar 290. When Jump command 296 is selected, a window partition 275 is opened. In window 275, the user is presented and may select from a variety of displayed options that include among others, the Directory command, the Index command, and the Guide command, which when selected, have the effect noted above. Additionally, the user can select a command termed Viewpath which will presents the keywords that currently

US 7,072,849 B1

21

make up the list of keywords associated with the user's Path command, and from which list the user can select a desired keyword. Still further, and with reference FIG. 11, which shows the sequence where a user offers a term to identify a subject of interest, the user may enter a keyword at display field 270 within window partition 275 as a "best guess" of the mnemonic character string that is assigned to a partitioned application the user desires (e.g., the user may input such english words as "news," "pet food," "games," etcetera). Where the user enters a character string it is displayed in field 270, and then searched by RS 400 native code (discussed below) against the sequence sets above noted to identify the object-id for the appropriate table of keywords (not shown) that RS 400 may request from host 205. While as noted above, a table may include 10 to 20 keywords, in the preferred embodiment, for the sake of speed and convenience, a typical keyword table includes approximately 12 keywords.

If the string entered by the user matches a keyword existing on one of the keyword tables, and is thus associated with a specific PTO, RS 400 fetches and displays associated objects of the partitioned applications and builds the entry page in accordance with the page composition dictated by the target PTO.

If the string entered by the user does not match a specific keyword, RS 400 presents the user with the option of displaying the table of keywords approximating the specific keyword. The approximate keywords are presented as initialized, cursorable selector fields of the type provided in connection with a Index command. The user may then move the cursor to the nearest approximation of the mnemonic he originally selected, and trigger navigation to the PTO associated with that keyword, navigation being as described hereafter in connection with the RS 400 native code.

If, after selecting the Jump command, the user selects the Index command, RS 400 will retrieve the keyword table residing at RS 400, and will again build a page with initialized, cursorable fields of keywords. The table fetched upon invoking the Index command will be comprised of alphabetic keywords that occur within the range of the keywords associated with the page template object (PTO) from which the user invoked the Index command. As discussed above, the user may select to navigate to any of this range of PTOs by selecting the relevant keyword from the display. Alternatively, the user can, thereafter, select another range of alphabetical keywords by entering an appropriate character string in a screen field provided or move forward or backward in the collection by selecting the corresponding option.

By selecting the Directory command, RS 400 can be caused to fetch a table of keywords, grouped by categories, to which the PTO of the current partitioned application (as specified by the object set field 630 of the current PEO) belongs. Particularly, by selecting the Directory command, RS 400, is causes to displays a series of screens each of which contains alphabetically arranged general subject categories from which the user may select. Following selection of a category, a series of keywords associated with the specified category are displayed in further screens together with descriptive statements about the application associated with the keywords. Thereafter, the user can, in the manner previously discussed with regard to the Index command, select from and navigate to the PTOs of keywords which are related to the present page set by subject.

The Guide command provides a navigation method related to a hierarchical organization of applications provided on network 10, and are described by a series of

22

sequentially presented overlaying windows of a type known in the art, each of which presents an increasing degree of detail for a particular subject area, terminating in a final window that gives keywords associated with the relevant applications. The Guide command makes use of the keyword segment which describes the location of the PTO in a hierarchy (referred to, in the preferred embodiment, as the "BFD," or Building-Floor-Department) as well as an associated keyword character string. The BFD describes the set of menus that are to be displayed on the screen as the sequence of pop-up windows. The Guide command may be invoked by requesting it from the Jump window described above, or by selecting the Menu command on Command Bar 290. As noted above, in the case of the Guide command, the PTO and object-ids for the application entry screen are directly associated with the graphic of the keyword presented in the final pop-up window. This enables direct access of the application entry screen without need to access the sequence set and keyword table, and thus, reduces response time by reducing the number of objects that must be processed at RS 400.

Activation of the Path command accesses the user's list of pre-selected keywords without their display, and permits the user to step through the list viewing the respective applications by repeatedly invoking the Path command. As will be appreciated, the user can set a priority for selecting keywords and viewing their associated applications by virtue of where on the list the user places the keywords. More specifically, if the user has several application of particular interest; e.g., news, weather, etc., the user can place them at the top of the list, and quickly step through them with the Path command. Further, the user can view and randomly access the keywords of his list with the Viewpath operation noted above. On activation of Viewpath, the user's Path keywords are displayed and the user can cursor through them in a conventional manner to select a desired one. Further, the user can amend the list as desired by changing the keywords on the list and/or adjusting their relative position. This is readily accomplished by entering the amendments to the list presented at the screen 414 with a series of amendment options presented in a conventional fashion with the list. As noted, the list may be personally selected by the user in the manner described, or created as a default by network 10.

Collectively, the Jump command, Index command, Directory command, Guide command, and Path command as described enable the user to quickly and easily ascertain the "location" of either the partitioned application presently displayed or the "location" of a desired partitioned application. "Location," as used in reference to the preferred embodiment means the specific relationships that a particular partitioned application bears to other such applications, and the method for selecting particular partitioned applications from such relationships. The techniques for querying a database of objects, embodied in network 10 is an advance over the prior art, insofar as no foreknowledge of either database structure or query technique or syntax is necessary, the structure and search techniques being made manifest to the user in the course of use of the commands.

#### RS Application Protocol

RS protocol defines the way the RS supports user application conversation (input and output) and the way RS 400 processes a partitioned application. Partitioned applications are constructed knowing that this protocol will be supported unless modified by the application. The protocol is illus-

US 7,072,849 B1

23

trated FIG. 6. The boxes in FIG. 6 identify processing states that the RS 400 passes through and the arrows indicate the transitions permitted between the various states and are annotated with the reason for the transition.

The various states are: (A) Initialize RS, (B) Process Objects, (C) Interpretively Execute Pre-processors, (D) Wait for Event, (E) Process Event, and (F) Interpretively Execute Function Extension and/or Post-processors.

The transitions between states are: (1a) Logon Page Template Object Identification (PTO-id), (1b) Object Identification, (2) Trigger Program Object identification (PO-id) & return, (3) Page Partition Template (PPT) or Window Stack Processing complete, (4) Event Occurrence, and (5) Trigger PO-id and Return.

Transition (1a) from Initialize RS (A) to Process Objects (B) occurs when an initialization routine passes the object-id of the logon PTO to object interpreter 435, when the service is first invoked. Transition (1b) from Process Event (E) to Process Objects (B) occurs whenever a navigation event causes a new page template object identification (PTO-id) to be passed to object interpreter 435; or when an open window event (verb or function key) occurs passing a window object-id to the object interpreter 435; or a close window event (verb or function key) occurs causing the current top-most window to be closed.

While in the process object state, object interpreter 435 will request any objects that are identified by external references in call segments. Objects are processed by parsing and interpreting the object and its segments according to the specific object architecture. As object interpreter 435 processes objects, it builds a linked list structure called a page processing table (PPT), shown in FIG. 10, to reflect the structure of the page, each page partition, Page Element Objects (PEOs) required, program objects (POs) required and each window object (WO) that could be called. Object interpreter 435 requests all objects required to build a page except objects that could be called as the result of some event, such as a HELP window object.

Transition (2) from Process Objects (B) to Interpretively Execute Pre-processors (C) occurs when the object interpreter 435 determines that a pre-processor is to be triggered. Object processor 436 then passes the object-id of the program object to the TBOL interpreter 438. TBOL interpreter 438 uses the RS virtual machine to interpretively execute the program object. The PO can represent either a selector or an initializer. When execution is complete, a transition automatically occurs back to Process Objects (B).

Selectors are used to dynamically link and load other objects such as PEOs or other PDOs based upon parameters that they are passed when they are called. Such parameters are specified in call segments or selector segments. This feature enables RS 400 to conditionally deliver information to the user base upon predetermined parameters, such as his personal demographics or locale. For example, the parameters specified may be the transaction codes required to retrieve the user's age, sex, and personal interest codes from records contained in user profiles stored at the switch/file server layer 200.

Initializers are used to set up the application processing environment for a partitioned application and determine what events RS 400 may respond to and what the action will be.

Transition (3) from Process Objects (B) to Wait for Event (D) occurs when object interpreter 435 is finished processing objects associated with the page currently being built or opening or closing a window on a page. In the Wait for Event state (D), an input manager, which in the preferred form

24

shown includes keyboard manager 434 seen in FIG. 8, accepts user inputs. All keystrokes are mapped from their physical codes to logical keystrokes by the Keyboard Manager 434, representing keystrokes recognized by the RS virtual machine.

When the cursor is located in a field of a page element, keystrokes are mapped to the field and the partitioned external variable (PEV) specified in the page element object (PEO) field definition segment by the cooperative action of keyboard manager, 434 and display manager 461. Certain inputs, such as RETURN or mouse clicks in particular fields, are mapped to logical events by keyboard manager 434, which are called completion (or commit) events. Completion events signify the completion of some selection or specification process associated with the partitioned application and trigger a partition level and/or page level post-processor to process the "action" parameters associated with the user's selection and commit event.

Such parameters are associated with each possible choice or input, and are set up by the earlier interpretive execution of an initializer pre-processor in state (C). Parameters usually specify actions to perform a calculation such as the balance due on an order of several items with various prices using sales tax for the user's location, navigate to PTO-id, open window WO-id or close window. Actions parameters that involve the specification of a page or window object will result in transition (1b) to the Process Objects (B) state after the post-processor is invoked as explained below.

Function keys are used to specify one or more functions which are called when the user strikes these keys. Function keys can include the occurrence of logical events, as explained above. Additionally, certain functions may be "filtered", that is, extended or altered by SET\_FUNCTION or TRIGGER\_FUNCTION verbs recognized by the RS virtual machine. Function keys cause the PO specified as a parameter of the verb to be interpretively executed whenever that function is called. Applications use this technique to modify or extend the functions provided by the RS.

Transition (5) from Process Event (E) to Interpretively Execute Pre-processors (F) occurs when Process Event State determines that a post-processor or function extension PDO is to be triggered. The id of the program object is then passed to the TBOL interpreter 438. The TBOL interpreter 438 uses the RS virtual machine to interpretively execute the PO. When execution is complete a transition automatically occurs back to Process Event (E).

#### Reception System Software

The reception system 400 software is the interface between the user of personal computer 405 and interactive network 10. The object of reception system software is to minimize mainframe processing, minimize transmission across the network, and support application extendibility and portability.

RS 400 software is composed of several layers, as shown in FIG. 7. It includes external software 451, which is composed of elements well known to the art such as device drivers, the native operating systems; i.e., MS-DOS, machine-specific assembler functions (in the preferred embodiment; e.g., CRC error checking), and "C" runtime library functions; native software 420; and partitioned applications 410.

Again with reference to FIG. 7, native software 420 is compiled from the "C" language into a target machine-specific executable, and is composed of two components: the service software 430 and the operating environment 450.

US 7,072,849 B1

25

Operating environment **450** is comprised of the Logical Operating System **432**, or LOS; and a multitasker **433**. Service software **430** provides functions specific to providing interaction between the user and interactive network **10**, while the operating environment **450** provides pseudo multitasking and access to local physical resources in support of service software **430**. Both layers of native software **420** contain kernel, or device independent functions **430** and **432**, and machine-specific or device dependent functions **433**. All device dependencies are in code resident at RS **400**, and are limited to implementing only those functions that are not common across machine types, to enable interactive network **10** to provide a single data stream to all makes of personal computer which are of the IBM or IBM compatible type. Source code for the native software **420** is included in parent application Ser. No. 388,156 now issued as U.S. Pat. No. 5,347,632, the contents of which patent are incorporated herein by reference. Those interested in a more detailed description of the reception system software may refer to the source code provided in the referenced patent.

Service software **430** is comprised of modules, which are device-independent software components that together obtain, interpret and store partitioned applications existing as a collection of objects. The functions performed by, and the relationship between, the service software **430** module is shown in FIG. **8** and discussed further below.

Through facilities provided by LOS **432** and multitasker **433**, here called collectively operating environment **450**, device-independent multitasking and access to local machine resources, such as multitasking, timers, buffer management, dynamic memory management, file storage and access, keyboard and mouse input, and printer output are provided. The operating environment **450** manages communication and synchronization of service software **430**, by supporting a request/response protocol and managing the interface between the native software **420** and external software **437**.

Applications software layer **410** consists of programs and data written in an interpretive language, "TRINTEX Basic Object Language" or "TBOL," described above. TBOL was written specifically for use in RS **400** and interactive network **10** to facilitate videotext-specific commands and achieve machine-independent compiling. TBOL is constructed as objects, which in interaction with one another comprise partitioned applications.

RS native software **420** provides a virtual machine interface for partitioned applications, such that all objects comprising partitioned applications "see" the same machine. RS native software provides support for the following functions: (1) keyboard and mouse input; (2) text and graphics display; (3) application interpretation; (4) application database management; (5) local application storage; (6) network and link level communications; (7) user activity data collection; and (8) advertisement management.

With reference to FIG. **8**, service software **430** is comprised of the following modules: start-up (not shown); keyboard manger **434**; object interpreter **435**; TBOL interpreter **438**; object storage facility **439**; display manager **461**; data collection manager **441**; ad manager **442**; object/communications manager interface **443**; link communications manager **444**; and fatal error manager **469**. Each of these modules has responsibility for managing a different aspect of RS **400**.

Startup reads RS **400** customization options into RAM, including modem, device driver and telephone number options, from the file CONFIG.SM. Startup invokes all RS **400** component startup functions, including navigation to

26

the first page, a logon screen display containing fields initialized to accept the user's id and password. Since Startup is invoked only at initialization, for simplicity, it has not been shown in FIG. **8**.

The principal function of keyboard manger **434** is to translate personal computer dependent physical input into a consistent set of logical keys and to invoke processors associated with these keys. Depending on the LOS key, and the associated function attached to it, navigation, opening of windows, and initiation of filter or post-processor TBOL programs may occur as the result input events handled by the keyboard manger **434**. In addition, keyboard manger **434** determines inter and intra field cursor movement, and coordinates the display of field text and cursor entered by the user with display manager **461**, and sends information regarding such inputs to data collection manager **441**.

Object interpreter **435** is responsible for building and recursively processing a table called the "Page Processing Table," or PPT. Object interpreter **435** also manages the opening and closing of windows at the current page. Object interpreter **435** is implemented as two sub-components: the object processor **436** and object scanner **437**.

Object processor **436** provides an interface to keyboard manger **434** for navigation to new pages, and for opening and closing windows in the current page. Object processor **436** makes a request to object storage facility **439** for a page template object (PTO) or window object (WO), as requested by keyboard manger **434**, and for objects and their segments which comprise the PTO or WO returned by object storage facility **439** to object processor **436**. Based on the particular segments comprising the object(s) making up the new PTO or WO, object processor **436** builds or adds to the page processing table (PPT), which is an internal, linked-list, global data structure reflecting the structure of the page or page format object (PFO), each page partition or page element object (PEO), and program objects (POs) required and each window object (WO) that could be called. Objects are processed by parsing and interpreting each object and its-segment(s) according to their particular structure as formalized in the data object architecture (DOA). While in the process object state, (state "B" of FIG. **6**), object processor **436** will request any objects specified by the PTO that are identified by external references in call segments (e.g. field level program call **518**, page element selector call **524**, page format call **526** program call **532**, page element call **522** segments) of such objects, and will, through a request to TBOL interpreter **438**, fire initializers and selectors contained in program data segments of all PTO constituent program objects, at the page, element, and field levels. Object processor **436** requests all objects required to build a page, except objects that could only be called as the result of some event external to the current partitioned application, such as a HELP window object. When in the course of building or adding to the PPT and opening/closing WOs, object processor encounters a call to an "ADSLLOT" object id, the next advertisement object id at ad manager **442** is fetched, and the identified advertisement object is retrieved either locally, if available, or otherwise from the network, so that the presentation data for the advertisement can be sent to display manager **461** along with the rest of the presentation data for the other objects to enable display to the user. Object processor **436** also passes to data collection manager **441** all object ids that were requested and object ids that were viewed. Upon completion of page or window processing, object processor **436** enters the wait for event state, and control is returned to keyboard manger **434**.

US 7,072,849 B1

27

The second component of object interpreter **435**, object scanner **437**, provides a file-like interface, shared with object storage facility **439**, to objects currently in use at RS **400**, to enable object processor **436** to maintain and update the PPT. Through facilities provided by object scanner **437**, object processor recursively constructs a page or window in the requested or current partitioned application, respectively.

Object storage facility **439** provides an interface through which object interpreter **435** and TBOL interpreter **438** either synchronously request (using the TBOL verb operator "GET") objects without which processing in either module cannot continue, or asynchronously request (using the TBOL verb operator "FETCH") objects in anticipation of later use. Object storage facility **439** returns the requested objects to the requesting module once retrieved from either local store **440** or interactive network **10**. Through control structures shared with the object scanner **437**, object storage facility determines whether the requested object resides locally, and if not, makes an attempt to obtain it from interactive network **10** through interaction with link communications manager **444** via object/communications manager interface **443**.

When objects are requested from object storage facility **439**, only the latest version of the object will be provided to guarantee currency of information to the user. Object storage facility **439** assures currency by requesting version verification from network **10** for those objects which are available locally and by requesting objects which are not locally available from delivery system **20** where currency is maintained.

Version verification increases response time. Therefore, not all objects locally available are version checked each time they are requested. Typically, objects are checked only the first time they are requested during a user session. However, there are occasions, as for example in the case of objects relating to news applications, where currency is always checked to assure integrity of the information.

The frequency with which the currency of objects is checked depends on factors such as the frequency of updating of the objects. For example, objects that are designated as ultrastable in a storage control parameter in the header of the object are never version checked unless a special version control object sent to the RS as part of logon indicates that all such objects must be version checked. Object storage facility **439** marks all object entries with such a stability category in all directories indicating that they must be version checked the next time they are requested.

Object storage facility **439** manages objects locally in local store **440**, comprised of a cache (segmented between available RAM and a fixed size disk file), and stage (fixed size disk file). Ram and disk cached objects are retained only during user sessions, while objects stored in the stage file are retained between sessions. The storage control field, located in the header portion of an object, described more fully hereafter as the object "storage candidacy", indicates whether the object is stageable, cacheable or trashable.

Stageable objects must not be subject to frequent change or update. They are retained between user sessions on the system, provided storage space is available and the object has not discarded by a least-recently-used (LRU) algorithm of a conventional type; e.g., see *Operating System Theory*, by Coffman, Jr. and Denning, Prentice Hall Publishers, New York, 1973, which in accordance with the design of network **10**, operates in combination with the storage candidacy value to determine the object storage priority, thus rendering the stage self-configuring as described more fully hereafter. Over time, the self-configuring stage will have the effect of retaining within local disk storage those objects which the

28

user has accessed most often. The objects retained locally are thus optimized to each individual user's usage of the applications in the system. Response time to such objects is optimized since they need not be retrieved from the interactive computer system.

Cacheable objects can be retained during the current user session, but cannot be retained between sessions. These objects usually have a moderate update frequency. Object storage facility **439** retains objects in the cache according to the LRU storage retention algorithm. Object storage facility **439** uses the LRU algorithm to ensure that objects that are least frequently used forfeit their storage to objects that are more frequently used.

Trashable objects can be retained only while the user is in the context of the partitioned application in which the object was requested. Trashable objects usually have a very high update frequency and must not be retained to ensure that the user has access to the most current data.

More particularly and, as noted above, in order to render a public informational and transactional network of the type considered here attractive, the network must be both economical to use and fast. That is to say, the network must supply information and transactional support to the user at minimal costs and with a minimal response time. These objectives are sought to be achieved by locating as many information and transactional support objects which the user is likely to request, as close to the user as possible; i.e., primarily at the user's RS **400** and secondarily at delivery system **20**. In this way, the user will be able to access objects required to support a desired application with minimal intervention of delivery system **20**, thus reducing the cost of the session and speeding the response time.

However, the number of objects that can be maintained at RS **400** is restricted by at least two factors: the RS **400** storage capacity; i.e., RAM and disk sizes, and the need to maintain the stored objects current.

In order to optimize the effectiveness of the limited storage space at RS **400**, the collection of objects is restricted to those likely to be requested by the user; i.e., tailored to the user's tastes—and to those least likely to be time sensitive; i.e., objects which are stable. To accomplish this, objects are coded for storage candidacy to identify when they will be permitted at RS **400**, and subject to the LRU algorithm to maintain presence at RS **400**. Additionally, to assure currency of the information and transaction support provided at RS **400**, objects are further coded for version identification and checking in accordance with a system of priorities that are reflected in the storage candidacy coding.

Specifically, to effect object storage management, objects are provided with a coded version id made up of the storage control byte and version control bytes identified above as elements of the object header, specifically, bytes **16** and **18** shown in FIG. **4b**. In preferred form, the version id is comprised of bytes **16** and **18** to define two fields, a first 13 bit field to identify the object version and a second three bite field to identify the object storage candidacy.

In this arrangement, the storage candidacy value of the object is addressed to not only the question of storage preference but also object currency. Specifically, the storage candidacy value establishes the basis upon which the object will be maintained at RS **400** and also identifies the susceptibility of the object to becoming stale by dictating when the object will be version checked to determine currency.

The version value of the object on the other hand, provides a parameter that can be checked against predetermined values available from delivery system **20** to deter-

US 7,072,849 B1

29

mine whether an object stored at RS 400 is sufficiently current to permit its continued use, or whether the object has become stale and needs to be replaced with a current object from delivery system 20.

Still further, object storage management procedure further includes use of the LRU algorithm, for combination with the storage and version coding to enable discarding of objects which are not sufficiently used to warrant retention, thus personalizing the store of objects at RS 400 to the user's tastes. Particularly, object storage facility 439, in accordance with the LRU algorithm maintains a usage list for objects. As objects are called to support the user's applications requests, the objects are moved to the top of a usage list. As other objects are called, they push previously called objects down in the list. If an object is pushed to the bottom of the list before being recalled, it will be forfeited from the list if necessary to make room for the next called object. As will be appreciated, should a previously called object be again called before it is displaced from the list, it will be promoted to the top of the list, and once more be subject to depression in the list and possible forfeiture as other objects are called.

As pointed out above, in the course of building the screens presented to the user, objects will reside at various locations in RS 400. For example, objects may reside in the RS 400 RAM where the object is supporting a particular application screen then running or in a cache maintained at either RAM or disk 424 where the object is being held for an executing application or staged on the fixed size file on disk 424 noted above where the object is being held for use in application likely to be called by the user in the future.

In operation, the LRU algorithm is applied to all these regions and serves to move an object from RAM cache to disk cache to disk file, and potentially off RS 400 depending on object usage.

With regard to the storage candidacy value, in this arrangement, the objects stored at RS 400 include a limited set of permanent objects; e.g., those supporting logon and logoff, and other non-permanent objects which are subject to the LRU algorithm to determine whether the objects should be forfeited from RS 400 as other objects are added. Thus, in time, and based on the operation of the LRU algorithm and the storage candidacy value, the collection of objects at RS 400 will be tailored to the usage characteristics of the subscriber; i.e., self-configuring.

More particularly, the 3-bit field of the version id that contains the storage candidacy parameter can have 8 different values. A first candidacy value is applied where the object is very sensitive to time; e.g., news items, volatile pricing information such as might apply to stock quotes, etc. In accordance with this first value, the object will not be permitted to be stored on RS 400, and RS 400 will have to request such objects from delivery system 20 each time it is accessed, thus, assuring currency. A second value is applied where the object is sensitive to time but less so than the first case; e.g., the price of apples in a grocery shopping application. Here, while the price might change from day to day, it is unlikely to change during a session. Accordingly the object will be permitted to persist in RAM or at the disk cache during a session, but will not be permitted to be maintained at RS 400 between sessions.

Continuing down the hierarchy of time sensitivity, where the object concerns information sufficiently stable to be maintained between sessions, a third storage candidacy value is set to permit the object to be stored at RS 400 between sessions, on condition that the object will be version check the first time it is accessed in a subsequent session. As will be appreciated, during a session, and under

30

the effect of the LRU algorithm, lack of use at RS 400 of the object may result in it being forfeited entirely to accommodate new objects called for execution at RS 400.

Still further, a fourth value of storage candidacy is applied where the object is considered sufficiently stable as not to require version checking between sessions; e.g., objects concerning page layouts not anticipated to change. In this case, the storage candidacy value may be encoded to permit the object to be retained from session to session without version checking. Here again, however, the LRU algorithm may cause the object to forfeit its storage for lack of use.

Where the object is of a type required to be stored at RS 400, as for example, objects needed to support standard screens, it is coded for storage between sessions and not subject to the LRU algorithm forfeiture. However, where such objects are likely to change in the future they may be required to be version checked the first time they are accessed in a session and thus be given a fifth storage candidacy value. If, on the other hand, the required stored object is considered likely to be stable and not require even version checking; e.g., logon screens, it will be coded with a sixth storage candidacy value for storage without version checking so as to create a substantially permanent object.

Continuing, where a RS 400 includes a large amount of combined RAM and disk capacity, it would permit more objects to be stored. However, if objects were simply coded in anticipation of the larger capacity, the objects would potentially experience difficulty, as for example, undesired forfeiture due to capacity limitations if such objects were supplied to RS 400 units having smaller RAM and disk sizes. Accordingly, to take advantage of the increased capacity of certain RS 400 units without creating difficulty in lower capacity units, objects suitable for storage in large capacity units can be so coded for retention between sessions with a seventh and eighth storage candidacy value depending upon whether the stored large capacity object requires version checking or not. Here, however, the coding will be interpreted by smaller capacity units to permit only cacheable storage to avoid undesirable forfeiture that might result from over filling the smaller capacity units.

Where an object is coded for no version checking need may nonetheless arise for a version check at some point. To permit version checking of such objects, a control object is provided at RS 400 that may be version checked on receipt of a special communication from delivery system 20. If the control object fails version check, then a one shot version checking attribute is associated with all existing objects in RS 400 that have no version checking attributes. Thereafter, the respective objects are version checked, the one shot check attribute is removed and the object is caused to either revert to its previous state if considered current or be replaced if stale.

Still further, objects required to be stored at RS 400 which are not version checked either because of lack of requirement or because of no version check without a control object, as described above, can accumulate in RS 400 as dead objects. To eliminate such accumulation, all object having required storage are version checked over time. Particularly, the least recently used required object is version checked during a session thus promoting the object to the top of the usage list if it is still to be retained at RS 400. Accordingly, one such object will be checked per session and over time, all required objects will be version checked thereby eliminating the accumulation of dead objects.

However, in order to work efficiently, the version check attribute of the object should be ignored, so that even required object can be version checked. Yet, in certain

US 7,072,849 B1

31

circumstances, e.g., during deployment of new versions of the reception system software containing new objects not yet supported on delivery system **20** which may be transferred to the fixed storage file of RS **400** when the new version is loaded, unconditional version checking may prematurely delete the object from the RS **400** as not found on delivery system **20**. To avoid this problem, a sweep control segment in the control object noted above can be used to act as a switch to turn the sweep of dead objects on and off.

With respect to version checking for currency, where an object stored at RS **400** is initially fetched or accessed during a session, a request to delivery system **20** is made for the object by specifying the version id of the object stored at RS **400**.

In response, delivery system **20** will advise the reception system **400** either that the version id of the stored object matches the currency value; i.e., the stored object is acceptable, or deliver a current object that will replace the stored object shown to be stale. Alternatively, the response may be that the object was not found. If the version of the stored object is current, the stored object will be used until verified again in accordance with its storage candidacy. If the stored object is stale, the new object delivered will replace the old one and support the desired screen. If the response is object not found, the stored object will be deleted.

Therefore, based on the above description, network **10** is seen to include steps for execution at storage facility **439** which enables object reception, update and deletion by means of a combination of operation of the LRU algorithm and interpretation of the storage candidacy and version control values. In turn, these procedures cooperate to assure a competent supply of objects at RS **400** so as to reduce the need for intervention of delivery system **20**, thus reducing cost of information supply and transactional support so as to speed the response to user requests.

TBOL interpreter **438** shown in FIG. **8** provides the means for executing program objects, which have been written using an interpretive language, TBOL described above. TBOL interpreter **438** interprets operators and operand contained in program object **508**, manages TBOL variables and data, maintains buffer and stack facilities, and provides a runtime library of TBOL verbs.

TBOL verbs provide support for data processing, program flow control, file management, object management, communications, text display, command bar control, open/close window, page navigation and sound. TBOL interpreter also interacts with other native modules through commands contained in TBOL verbs. For example: the verb "navigate" will cause TBOL interpreter **438** to request object interpreter **435** to build a PPT based on the PTO id contained in the operand of the NAVIGATE verb; "fetch" or "GET" will cause TBOL interpreter **438** to request an object from object storage facility **439**; "SET\_FUNCTION" will assign a filter to events occurring at the keyboard manger **434**; and "FORMAT," "SEND," and "RECEIVE" will cause TBOL interpreter **438** to send application level requests to object/communications manager interface **433**.

Data areas managed by TBOL interpreter **438** and available to TBOL programs are Global External Variables (GEVs), Partition External Variables (PEVs), and Runtime Data Arrays (RDAs).

GEVs contain global and system data, and are accessible to all program objects as they are executed. GEVs provide a means by which program objects may communicate with other program objects or with the RS native code, if declared in the program object. GEVs are character string variables that take the size of the variables they contain. GEVs may

32

preferably contain a maximum of 32,000 variables and are typically used to store such information as program return code, system date and time, or user sex or age. TBOL interpreter **438** stores such information in GEVs when requested by the program which initiated a transaction to obtain these records from the RS or user's profile stored in the interactive system.

Partition external variables (PEVs) have a scope restricted to the page partition on which they are defined. PEVs are used to hold screen field data such that when PEOs and window objects are defined, the fields in the page partitions with which these objects are to be associated are each assigned to a PEV. When applications are executed, TBOL interpreter **438** transfers data between screen fields and their associated PEV. When the contents of a PEV are modified by user action or by program direction, TBOL interpreter **428** makes a request to display manager **461** to update the screen field to reflect the change. PEVs are also used to hold partition specific application data, such as tables of information needed by a program to process an expected screen input.

Because the scope of PEVs is restricted to program objects associated with the page partition in which they are defined, data that is to be shared between page partitions or is to be available to a page-level processor must be placed in GEVs or RDAs.

RDAs are internal stack and save buffers used as general program work areas. RDAs are dynamically defined at program object "runtime" and are used for communication and transfer of data between programs when the data to be passed is not amenable to the other techniques available. Both GEVs and RDAs include, in the preferred embodiment, 8 integer registers and 8 decimal registers. Preferably, there are also 9 parameter registers limited in scope to the current procedure of a program object.

All variables may be specified as operand of verbs used by the virtual machine. The integer and decimal registers may be specified as operand for traditional data processing. The parameter registers are used for passing parameters to "called" procedures. The contents of these registers are saved on an internal program stack when a procedure is called, and are restored when control returns to the "calling" procedure from the "called" procedure.

TBOL interpreter **438**, keyboard manger **434**, object interpreter **435**, and object storage facility **439**, together with device control provided by operating environment **450**, have principal responsibility for the management and execution of partitioned applications at the RS **400**. The remaining native code modules function in support and ancillary roles to provide RS **400** with the ability display partitioned applications to the user (display manager **461**), display advertisements (ad manager **442**), to collect usage data for distribution to interactive network **10** for purposes of targeting such advertisements (data collection manager **441**), and prepare for sending, and send, objects and messages to interactive network **10** (object/communications manager interface **443** and link communications manager **444**) Finally, the fatal error manager exists for one purpose: to inform the user of RS **400** and transmit to interactive network **10** the inability of RS **400** to recover from a system error.

Display manager **461** interfaces with a decoder using the North American Presentation Level Protocol Syntax (NAPLPS), a standard for encoding graphics data, or text code, such as ASCII, which are displayed on monitor **412** of the user's personal computer **405** as pictorial codes. Codes for other presentation media, such as audio, can be specified by

US 7,072,849 B1

33

using the appropriate type code in the presentation data segments. Display manager **461** supports the following functions: send NAPLPS strings to the decoder; echo text from a PEV; move the cursor within and between fields; destructive or non-destructive input field character deletion; “ghost” and “unghost” fields (a ghosted field is considered unavailable, unghosted available); turn off or on the current field cursor; open, close, save and restore bit maps for a graphics window; update all current screen fields by displaying the contents of their PEVs, reset the NAPLPS decoder to a known state; and erase an area of the screen by generating and sending NAPLPS to draw a rectangle over that area. Display manager **461** also provides a function to generate a beep through an interface with a machine-dependent sound driver.

In accordance with the method of the present invention, Ad manager **442** is invoked by object interpreter **435** to return the object id of the next available advertisement to be displayed. Ad manager **442** maintains a queue of advertising object id’s targeted to the specific user currently accessing interactive network **10**. Advertising objects are pre-fetched from interactive system **10** from a personalized queue of advertising ids that is constructed using data previously collected from user generated events and/or reports of objects used in the building of pages or windows, compiled by data collection manager **466** and transmitted to interactive system **10**.

Advertising objects **510** are PEOs that, through user invocation of a “LOOK” command, cause navigation to partitioned applications that may themselves support, for example, ordering and purchasing of merchandise.

An advertising object id list, or “ad queue,” is requested in a transaction message to delivery system **20** by ad manager **442** immediately after the initial logon response. The logon application at RS **400** places the advertising list in a specific RS global storage area called a SYS\_GEV (system global external variable), which is accessible to all applications as well as to the native RS code). The Logon application also obtains the first two ad object id’s from the queue and provides them to object storage facility **439** so the advertising objects can be requested. However, at logon, since no advertising objects are available at RS local storage facilities **440**, ad objects, in accordance with the described storage candidacy, not being retained at the reception system between sessions, they must be requested from interactive network **10**.

In a preferred embodiment, the following parametric values are established for ad manager **442**: advertising object is queue capacity, replenishment threshold for advertising object id’s and replenishment threshold for number of outstanding pre-fetched advertising objects. These parameters are set up in GEVs of the RS virtual machine by the logon application program object from the logon response from high function system **110**. The parameters are then also accessible to the ad manager **442**. Preferred values are an advertising queue capacity of 15, replenishment value of 10 empty queue positions and a pre-fetched advertising object threshold of 3.

Ad manager **442** pre-fetches advertising objects by passing advertising object id’s from the advertising queue to object storage facility **439** which then retrieves the object from the interactive system if the object is not available locally. Advertising objects are pre-fetched, so they are available in RS local store **440** when requested by object interpreter **435** as it builds a page. The ad manager **442** pre-fetches additional advertising objects whenever the number of pre-fetched advertising objects not called by

34

object interpreter **435**; i.e. the number of remaining advertising objects, falls below the pre-fetch advertising threshold.

Whenever the advertising object id queue has more empty positions than replenishment threshold value, a call is made to the advertising object id queue application in high function system **110** shown in FIG. 2, via object/communications manager interface **443** for a number of advertising object id’s equal to the threshold value. The response message from system **110** includes a list of advertising object id’s, which ad manager **442** enqueues.

Object interpreter **435** requests the object id of the next advertising object from ad manager **442** when object interpreter **435** is building a page and encounters an object call for a partition and the specified object-id equals the code word, “ADSLLOT.” If this is the first request for an advertising object id that ad manager **442** has received during this user’s session, ad manager **442** moves the advertising object id list from the GEV into its own storage area, which it uses as an advertising queue and sets up its queue management pointers, knowing that the first two advertising objects have been pre-fetched.

Ad manager **442** then queries object storage facility **439**, irrespective of whether it was the first request of the session. The query asks if the specified advertising object id pre-fetch has been completed, i.e., is the object available locally at the RS. If the object is available locally, the object-id is passed to object interpreter **435**, which requests it from object storage facility **439**. If the advertising object is not available in local store **440**, ad manager **442** attempts to recover by asking about the next ad that was pre-fetched. This is accomplished by swapping the top and second entry in the advertising queue and making a query to object storage facility **439** about the new top advertising object id. If that object is not yet available, the top position is swapped with the third position and a query is made about the new top position.

Besides its ability to provide advertising that have been targeted to each individual user, two very important response time problems have been solved by ad manager **442** of the present invention. The first is to eliminate from the new page response time the time it takes to retrieve an advertising object from the host system. This is accomplished by using the aforementioned pre-fetching mechanism.

The second problem is caused by pre-fetching, which results in asynchronous concurrent activities involving the retrieval of objects from interactive system **10**. If an advertising object is pre-fetched at the same time as other objects required for a page are requested, the transmission of the advertising object packets could delay the transmission of the other objects required to complete the current page by the amount of time required to transmit the advertising object(s). This problem is solved by the structuring the requests from object interpreter **435** to the ad manager **442** in the following way:

1. Return next object id of pre-fetched advertising object & pre-fetch another;
2. Return next advertising object id only; and
3. Pre-fetch next advertising object only.

By separating the function request (1) into its two components, (2) and (3), object interpreter **435** is now able to determine when to request advertising object id’s and from its knowledge of the page build process, is able to best determine when another advertising object can be pre-fetched, thus causing the least impact on the page response time. For example, by examining the PPT, object interpreter **435** may determine whether any object requests are out-

US 7,072,849 B1

35

standing. If there are outstanding requests, advertising request type 2 would be used. When all requested objects are retrieved, object interpreter **435** then issues an advertising request type 3. Alternatively, if there are no outstanding requests, object interpreter **435** issues an advertising request type 1. This typically corresponds to the user's "think time" while examining the information presented and when RS **400** is in the Wait for Event state (D).

Data collection manager **441** is invoked by object interpreter **435** and keyboard manager **434** to keep records about what objects a user has obtained (and, if a presentation data segment **530** is present, seen) and what actions users have taken (e.g. "NEXT," "BACK," "LOOK," etc.).

The data collection events that are to be reported during the user's session are sensitized during the logon process. The logon response message carries a data collection indicator with bit flags set to "on" for the events to be reported. These bit flags are enabled (on) or disabled (off) for each user based on information contained in the user's profile stored and sent from high function host **110**. A user's data collection indicator is valid for the duration of his session. The type of events to be reported can be changed at will in the host data collection application. However, such changes will affect only users who logon after the change.

Data collection manager **441** gathers information concerning a user's individual system usage characteristics. The types of informational services accessed, transactions processed, time information between various events, and the like are collected by data collection manager **441**, which compiles the information into message packets (not shown). The message packets are sent to network **10** via object/communication manager interface **443** and link communications manager **444**. Message packets are then stored by high function host **110** and sent to an offline processing facility for processing. The characteristics of users are ultimately used as a means to select or target various display objects, such as advertising objects, to be sent to particular users based on consumer marketing strategies, or the like, and for system optimization.

Object/communications manager interface **443** is responsible for sending and receiving DIA (Data Interchange Architecture described above) formatted messages to or from interactive network **10**. Object/communications manager **443** also handles the receipt of objects, builds a DIA header for messages being sent and removes the header from received DIA messages or objects, correlates requests and responses, and guarantees proper block sequencing. Object/communications manager interface **443** interacts with other native code modules as follows: object/communications manager **443** (1) receives all RS **400** object requests from object storage facility **439**, and forwards objects received from network **10** via link communications manager **444** directly to the requesting modules; (2) receives ad list requests from ad manager **442**, which thereafter periodically calls object/communications manager **443** to receive ad list responses; (3) receives data collection messages and send requests from data collection manager **441**; (4) receives application-level requests from TBOL interpreter **438**, which also periodically calls object/communications manager interface **443** to receive responses (if required); and (5) receives and sends DIA formatted objects and messages from and to link communications manager **444**.

Object/communications manager interface **443** sends and receives DIA formatted messages on behalf of TBOL interpreter **438** and sends object requests and receives objects on behalf of object storage facility **439**. Communication packets received containing parts of requested objects are passed

36

to object storage facility **439** which assembles the packets into the object before storing it. If the object was requested by object interpreter **435**, all packets received by object storage facility **439** are also passed to object interpreter **435** avoiding the delay required to receive an entire object before processing the object. Objects which are pre-fetched are stored by object storage facility **439**.

Messages sent to interactive network **10** are directed via DIA to applications in network **10**. Messages may include transaction requests for records or additional processing of records or may include records from a partitioned application program object or data collection manager **441**. Messages to be received from network **10** usually comprise records requested in a previous message sent to network **10**. Requests received from object storage facility **439** include requests for objects from storage in interactive system **10**. Responses to object requests contain either the requested object or an error code indicating an error condition.

Object/communications manager **443** is normally the exclusive native code module to interface with link communications manager **444** (except in the rare instance of a fatal error). Link communications manager **444** controls the connecting and disconnecting of the telephone line, telephone dialing, and communications link data protocol. Link communications manager **444** accesses network **10** by means of a communications medium (not shown) link communications manager **444**, which is responsible for a dial-up link on the public switched telephone network (PSTN). Alternatively, other communications means, such as cable television or broadcast media, may be used. Link communications manager **444** interfaces with TBOL interpreter for connect and disconnect, and with interactive network **10** for send and receive.

Link communications manager **444** is subdivided into modem control and protocol handler units. Modem control (a software function well known to the art) hands the modem specific handshaking that occurs during connect and disconnect. Protocol handler is responsible for transmission and receipt of data packets using the TCS (TRINTEX Communications Subsystem) protocol (which is a variety of OSI link level protocol, also well known to the art).

Fatal error manager **469** is invoked by all reception system components upon the occurrence of any condition which precludes recovery. Fatal error manager **469** displays a screen to the user with a textual message and an error code through display manager **461**. Fatal error manager **469** sends an error report message through the link communications manager **444** to a subsystem of interactive network **10**.

The source code for the reception system software as noted above is described in parent application Ser. No. 388,156 filed Jul. 28, 1989, now issued as U.S. Pat. No. 5,347,632, the contents of which are incorporated herein by reference.

#### Sample Application

Page **255** illustrated in FIG. **3b** corresponds to a partitioned application that permit's a user to purchase apples. It shows how the monitor screen **414** of the reception system **400** might appear to the user. Displayed page **255** includes a number of page partitions and corresponding page elements.

The page template object (PTO) **500** representing page **255** is illustrated in FIG. **9**. PTO **500** defines the composition of the page, including header **250**, body **260**, display fields **270**, **271**, **272**, advertising **280**, and command bar **290**. Page element objects (PEOs) **504** are associated with page parti-

US 7,072,849 B1

37

tions numbered; e.g., **250**, **260**, **280**. They respectively, present information in the header **250**, identifying the page topic as ABC APPLES; in the body **260**, identifying the cost of apples; and prompt the user to input into fields within body **260** the desired number of apples to be ordered. In advertising **280**, presentation data and a field representing a post-processor that will cause the user to navigate to a targetable advertising, is presented.

In FIG. 9, the structure of PTO **500** can be traced. PTO **500** contains a page format call segment **526**, which calls page format object (PFO) **502**. PFO **502** describes the location and size of partitions on the page and numbers assigned to each partition. The partition number is used in page element call segments **522** so that an association is established between a called page element object (PEO) **504** and the page partition where it is to be displayed. Programs attached to this PEO can be executed only when the cursor is in the page partition designated within the PEO.

PTO **500** contains two page element call segments **522**, which reference the PEOs **504** for partitions **250** and **260**. Each PEO **504** defines the contents of the partition. The header in partition **250** has only a presentation data segment **530** in its PEO **504**. No input, action, or display fields are associated with that partition.

The PEO **504** for partition **260** contains a presentation data segment **530** and field definition segments **516** for the three fields that are defined in that partition. Two of the fields will be used for display only. One field will be used for input of user supplied data.

In the example application, the PEO **504** for body partition **260** specifies that two program objects **508** are part of the body partition. The first program, shown in Display field **270**, **271**, **272**, is called an initializer and is invoked unconditionally by TBOL interpreter **438** concurrently with the display of presentation data for the partition. In this application, the function of the initializer is represented by the following pseudo-code:

1. Move default values to input and display fields;
2. "SEND" a transaction to the apple application that is resident on interactive system **10**;
3. "RECEIVE" the result from interactive system **10**; i.e. the current price of an apple;
4. Move the price of an apple to PEV **271** so that it will be displayed;
5. Position the cursor on the input field; and
6. Terminate execution of this logic.

The second program object **508** is a field post-processor. It will be invoked conditionally, depending upon the user keystroke input. In this example, it will be invoked if the user changes the input field contents by entering a number. The pseudo code for this post-processor is as follows:

1. Use the value in PEV **270** (the value associated with the data entered by the user into the second input data field **270**) to be the number of apples ordered.
2. Multiply the number of apples ordered times the cost per apple previously obtained by the initializer;
3. Construct a string that contains the message "THE COST OF THE APPLES YOU ORDERED IS \$45.34";
4. Move the string into PEV **272** so that the result will be displayed for the user; and
5. Terminate execution of this logic.

The process by which the "APPLES" application is displayed, initialized, and run is as follows.

The "APPLES" application is initiated when the user navigates from the previous partitioned application, with the navigation target being the object id of the "APPLES" PTO **500** (that is, object id ABC1). This event causes keyboard

38

manager **434** to pass the PTO object id, ABC1 (which may, for example, have been called by the keyword navigation segment **520** within a PEO **504** of the previous partitioned application), to object interpreter **435**. With reference to the RS application protocol depicted in FIG. 6, when the partitioned application is initiated, RS **400** enters the Process Object state (B) using transition (1). Object interpreter **435** then sends a synchronous request for the PTO **500** specified in the navigation event to object storage facility **439**. Object storage facility **439** attempts to acquire the requested object from local store **440** or from delivery system **20** by means of object/communication manager **443**, and returns an error code if the object cannot be acquired.

Once the PTO **500** is acquired by object/communications manager **443**, object interpreter **435** begins to build PPT by parsing PTO **500** into its constituent segment calls to pages and page elements, as shown in FIG. 4d and interpreting such segments. PFO and PEO call segments **526** and **522** require the acquisition of the corresponding objects with object id's <ABCF>, <ABCX> and <ABCY>. Parsing and interpretation of object ABCY requires the further acquisition of program objects <ABCI> and <ABCJ>.

During the interpretation of the PEOs **504** for partitions **250** and **260**, other RS **400** events are triggered. This corresponds to transition (2) to interpret pre-processors state (C) in FIG. 6. Presentation data **530** is sent to display manager **461** for display using a NAPLPS decoder within display manager **461**, and, as the PEO <ABCY> for partition **260** is parsed and interpreted by object interpreter **435**, parameters in program call segment **532** identify the program object <ABCI> as an initializer. Object interpreter **435** obtains the program object from object storage facility **439**, and makes a request to TBOL interpreter **438** to execute the initializer program object **508** <ABCI>. The initializer performs the operations specified above using facilities of the RS virtual machine. TBOL interpreter **438**, using operating environment **450**, executes initializer program object **506** <ABCI>, and may, if a further program object **508** is required in the execution of the initializer, make a synchronous application level object request to object storage facility **439**. When the initializer terminates, control is returned to object interpreter **435**, shown as the return path in transition (2) in FIG. 6.

Having returned to the process object state (B), object processor **435** continues processing the objects associated with PTO <ABCI>. Object interpreter continues to construct the PPT, providing RS **400** with an environment for subsequent processing of the PTO <ABCI> by pre-processors and post-processors at the page, partition, and field levels. When the PPT has been constructed and the initializer executed, control is returned to keyboard manager **434**, and the RS enters the wait for event (E) State, via transition (4), as shown in FIG. 6.

In the wait for event state, the partitioned application waits for the user to create an event. In any partitioned application, the user has many options. For example, the user may move the cursor to the "JUMP" field **296** on the command bar **290**, which is outside the current application, and thus cause subsequent navigation to another application. For purposes of this example, it is assumed that the user enters the number of apples he wishes to order by entering a digit in display field **271**.

Keyboard manager **434** translates the input from the user's keyboard to a logical representation independent of any type of personal computer. Keyboard manager **434** saves the data entered by the user in a buffer associated with the current field defined by the location of the cursor. The

US 7,072,849 B1

39

buffer is indexed by its PEV number, which is the same as the field number assigned to it during the formation of the page element. Keyboard manager **434** determines for each keystroke whether the keystroke corresponds to an input event or to an action or completion event. Input events are logical keystrokes and are sent by keyboard manager to display manager **461**, which displays the data at the input field location. Display manager **461** also has access to the field buffer as indexed by its PEV number.

The input data are available to TBOL interpreter **438** for subsequent processing. When the cursor is in a partition, only the PEVs for that partition are accessible to the RS virtual machine. After the input from the user is complete (as indicated by a user action such as pressing the RETURN key or entry of data into a field with an action attribute), RS **400** enters the Process Event state (E) via transition (4).

For purposes of this example, let us assume that the user enters the digit "5" in input field **270**. A transition is made to the process event state (E). Keyboard manager **434** and display manager **437** perform a number of actions, such as the display of the keystroke on the screen, the collection of the keystroke for input, and optionally, the validation of the keystroke, i.e. numeric input only in numeric fields. When the keystroke is processed, a return is made to the wait for event state (D) Edit attributes are specified in the field definition segment.

Suppose the user inputs a "6" next. A transition occurs to the PE state and after the "6" is processed, the Wait for Event (D) state is reentered. If the user hits the "completion" key (e.g., ENTER) the Process Event (E) state will be entered. The action attributes associated with field **272** identify this as a system event to trigger post-processor program object <ABCJ>. When the interpretive execution of program object <ABCJ> is complete, the wait for event state (D) will again be entered. The user is then free to enter another value in the input field, or select a command bar function and exit the apples application.

While this invention has been described in its preferred form, it will be appreciated that changes may be made in the form, construction, procedure and arrangement of its various elements and steps without departing from its spirit or scope.

We claim:

1. A method for presenting advertising obtained from a computer network, the network including a multiplicity of user reception systems at which respective users can request applications, from the network, that include interactive services, the respective reception systems including a monitor at which at least the visual portion of the applications can be presented as one or more screens of display, the method comprising the steps of:

- a. structuring applications so that they may be presented, through the network, at a first portion of one or more screens of display; and
- b. structuring advertising in a manner compatible to that of the applications so that it may be presented, through the network, at a second portion of one or more screens of display concurrently with applications, wherein structuring the advertising includes configuring the advertising as objects that include advertising data and;
- c. selectively storing advertising objects at a store established at the reception system.

2. The method of claim 1 wherein storing advertising objects at the reception system includes replenishing the store of advertising objects from the network when the store of advertising objects falls below a predetermined level.

3. The method of claim 2 wherein storing advertising objects at the reception system includes storing advertising

40

object identifications at the reception system, and wherein the storing of advertising object identification is based on an establishing of a characterization for the respective reception system users.

4. The method of claim 3 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on the applications requested by the respective users.

5. The method of claim 3 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on the demographic data for the respective users.

6. The method of claim 3 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on data concerning the geographical location of the respective user's reception system.

7. The method of claim 3 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on a combination of data concerning user application requests, user demographics and geographical location of the respective user's reception system.

8. A method for presenting advertising in a computer network, the network including a multiplicity of user reception systems at which respective users can request applications that include interactive services, the method comprising the steps of:

- a. compiling data concerning the respective users;
- b. establishing characterizations for respective users based on the compiled data; and
- c. structuring advertising so that it may be selectively supplied to and retrieved at the reception systems for presentation to the respective users in accordance with the characterizations established for the respective reception system users, wherein structuring advertising includes supplying advertising data to the reception system and storing a predetermined amount of the advertising data in a store established at the respective reception systems.

9. The method of claim 8 wherein supplying advertising data to the reception system includes pre-fetching advertising data from the network when the store of advertising data falls below a predetermined level.

10. The method of claim 9 wherein pre-fetching advertising data is dependent on the size of the advertising data store.

11. The method of claim 10 wherein storing advertising data at the reception system includes maintaining a list identifying the advertising data to be presented.

12. The method of claim 8 wherein the supplying of advertising data to the reception system for presentation includes the reception system requesting advertising data from the network when advertising data sought to be presented is unavailable at the reception system.

13. A method for presenting advertising in a computer network, the network including a multiplicity of user reception systems at which respective users can request applications that include interactive services, the respective reception systems including a monitor at which at least the visual portion of the applications can be presented as one or more screens of display, the method comprising the steps of:

- a. structuring applications so that they may be presented at a first portion of one or more screens of display;
- b. configuring the advertising as objects that include advertising data,

US 7,072,849 B1

41

- c. structuring the advertising objects in a manner compatible to that of the applications so that advertising data from an advertising object may be presented at a second portion of one or more screens of display concurrently with applications, and;
- d. selectively storing advertising objects at a store established at the reception system.

14. A method for presenting advertising obtained from a computer network, the network including a multiplicity of user reception systems at which respective users can request applications from the network that include interactive services, the respective reception systems including a monitor at which at least the visual portion of the applications can be presented as one or more screens of display, the method comprising the steps of:

- a. structuring applications so that a user requested application may be presented, through the network, at a first portion of one or more screens of display;
- b. separately structuring the advertising in a manner compatible to that of the applications so that advertising may be presented, through the network, at a second portion of one or more screens of display concurrently with any one of a plurality of user requested applications,
- c. configuring the advertising as objects that include advertising data, and
- d. selectively storing advertising objects at a store established at the reception system.

15. The method of claim 14 wherein storing advertising objects at the reception system includes replenishing the store of advertising objects from the network when the store of advertising objects falls below a predetermined level.

16. The method of claim 15 wherein storing advertising objects at the reception system includes storing advertising object identifications at the reception system, and wherein the storing of advertising object identification is based on an establishing of a characterization for the respective reception system users.

17. The method of claim 16 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on the applications requested by the respective users.

18. The method of claim 16 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on the demographic data for the respective users.

19. The method of claim 16 wherein establishing the characterization for the respective reception system users

42

includes basing the characterization at least in part on data concerning the geographical location of the respective user's reception system.

20. The method of claim 16 wherein establishing the characterization for the respective reception system users includes basing the characterization at least in part on a combination of data concerning user application requests, user demographics and geographical location of the respective user's reception system.

21. A method for presenting advertising obtained from a computer network, the network including a multiplicity of user reception systems at which respective users can request, from the network, applications that include interactive services, the method comprising the steps of:

- a. compiling data concerning the respective users;
- b. establishing characterizations for respective users based on the compiled data; and
- c. structuring advertising separately from the applications so that the advertising may be selectively supplied, through the network, to and retrieved at the reception systems for presentation to the respective users along with a requested application in accordance with the characterizations established for the respective reception system users,

wherein supplying advertising data to the reception system includes storing a predetermined amount of the advertising data in a store established at the respective reception systems.

22. The method of claim 21 wherein supplying advertising data to the reception system includes pre-fetching advertising data from the network when the store of advertising data falls below a predetermined level.

23. The method of claim 22 wherein pre-fetching advertising data is dependent on the size of the advertising data store.

24. The method of claim 23 wherein storing advertising data at the reception system includes maintaining a list identifying the advertising data to be presented.

25. The method of claim 21 wherein the supplying of advertising data to the reception system for presentation includes the reception system requesting advertising data from the network when advertising data sought to be presented is unavailable at the reception system.

## Inline Community Preview

Inline Community Preview helps buyers see new developments take shape.

Share     

Home shoppers want to visualize life in a new home community — and understand its context within the surrounding neighborhood — even if you only have a partially completed lot on display. Home shoppers are hungry for visuals, and they expect every detail to be at their fingertips so they feel empowered to take that next step and contact a builder for a community tour.

We have good news for builders: Promoted Communities is launching a new feature — called Inline Community Preview — that offers builder marketers an enhanced approach to highlighting a community on Zillow's map search.

Inline Community Preview makes discovery and exploration simple. Buyers shopping on Zillow see a visually rich preview of all the new construction lots and future home sites in your communities. It lets the individual lots, streets and community take shape, so that home shoppers understand what to expect.

By leveraging [Zillow Group Advantage Program](#) partner [Alpha Vision](#), we're able to show overlays that grab the buyer's attention on the map view. Alpha Vision builds the community preview with site maps provided directly from the builder. These then become an actual layer on top of existing maps to offer home shoppers a better visual experience.

Use the slider below to see Inline Community Preview (with [Lot Availability](#)) in action:

"One of the challenges of existing views is the use of outdated aerial photography, which often shows new homes sitting on an undeveloped site far from the latest state of development," said Marc Lamoureux, chief executive officer and founder at Alpha Vision. "With Inline Community Preview, a color homesite overlay is tastefully placed over the map — providing a sense of community and appeal, encouraging home shoppers to contact the builder on the Zillow listing and visit the community."

Consumers have high expectations when it comes to online shopping. As you work to [enhance your listing content](#) with powerful descriptions, videos and photos, your community visualizations can also be elevated. The more inventory is displayed, reflecting current phases of development, the more prospective buyers feel informed and empowered — and this translates into meaningful engagement.

Ready to learn more? Contact your Zillow Group representative directly or [email us](#) for information on how to integrate Inline Community Preview into your listings.

(57) **ABSTRACT**

A method, system, apparatus, and computer program product are presented to support computing systems of different enterprises that interact within a federated computing environment. Federated single-sign-on operations can be initiated at the computing systems of federation partners on behalf of a user even though the user has not established a user account at a federation partner prior to the initiation of the single-sign-on operation. For example, an identity provider can initiate a single-sign-on operation at a service provider while attempting to obtain access to a controlled resource on behalf of a user. When the service provider recognizes that it does not have a linked user account for the user that allows for a single-sign-on operation with the identity provider, the service provider creates a local user account. The service provider can also pull user attributes from the identity provider as necessary to perform the user account creation operation.

# **METHOD AND SYSTEM FOR A RUNTIME USER ACCOUNT CREATION OPERATION WITHIN A SINGLE-SIGN-ON PROCESS IN A FEDERATED COMPUTING ENVIRONMENT**

## **BACKGROUND OF THE INVENTION**

### **1. Field of the Invention**

The present invention relates to an improved data processing system and, in particular, to a method and apparatus for multicomputer data transferring. Still more particularly, the present invention is directed to networked computer systems.

### **2. Description of Related Art**

Enterprises generally desire to provide authorized users with secure access to protected resources in a user-friendly manner throughout a variety of networks, including the Internet. Although providing secure authentication mechanisms reduces the risks of unauthorized access to protected resources, those authentication mechanisms may become barriers to accessing protected resources. Users generally desire the ability to change from interacting with one application to another application without regard to authentication barriers that protect each particular system supporting those applications.

As users get more sophisticated, they expect that computer systems coordinate their actions so that burdens on the user are reduced. These types of expectations also apply to authentication processes. A user might assume that once he or she has been authenticated by some computer system, the authentication should be valid throughout the user's working session, or at least for a particular period of time, without regard to the various computer architecture boundaries that are almost invisible to the user. Enterprises generally try to fulfill these expectations in the operational characteristics of their deployed systems, not only to placate users but also to increase user efficiency, whether the user efficiency is related to employee productivity or customer satisfaction.

More specifically, with the current computing environment in which many applications have a Web-based user interface that is accessible through a common browser, users expect more user-friendliness and low or infrequent barriers to movement from one Web-based application to another. In this context, users are coming to expect the ability to jump from interacting with an application on one Internet domain to another application on another domain without regard to the authentication barriers that protect each particular domain. However, even if many systems provide secure authentication through easy-to-use, Web-based interfaces, a user may still be forced to reckon with multiple authentication processes that stymie user access across a set of domains. Subjecting a user to multiple authentication processes in a given time frame may significantly affect the user's efficiency.

For example, various techniques have been used to reduce authentication burdens on users and computer system administrators. These techniques are generally described as "single-sign-on" (SSO) processes because they have a common purpose: after a user has completed a sign-on operation, i.e. been authenticated, the user is subsequently not required to perform another authentication operation. Hence, the goal is that the user would be required to complete only one authentication process during a particular user session.

To reduce the costs of user management and to improve interoperability among enterprises, federated computing spaces have been created. A federation is a loosely coupled affiliation of enterprises which adhere to certain standards of interoperability; the federation provides a mechanism for trust among those enterprises with respect to certain compu-

2

tational operations for the users within the federation. For example, a federation partner may act as a user's home domain or identity provider. Other partners within the same federation may rely on the user's identity provider for primary management of the user's authentication credentials, e.g., accepting a single-sign-on token that is provided by the user's identity provider.

As enterprises move to support federated business interactions, these enterprises should provide a user experience that reflects the increased cooperation between two businesses. As noted above, a user may authenticate to one party that acts as an identity provider and then single-sign-on to a federated business partner that acts as a service provider. In conjunction with single-sign-on functionality, additional user lifecycle functionality, such as single-sign-off, user provisioning, and account linking/delinking, should also be supported.

Single-sign-on solutions require that a user be identifiable in some form or another at both an identity provider and a service provider; the identity provider needs to be able to identify and authenticate a user, and the service provider needs to be able to identify the user based on some form of assertion about the user in response to a single-sign-on request. Various prior art single-sign-on solutions, e.g., such as those described in the Liberty Alliance ID-FF specifications, require that a user have an authenticatable account at both an identity provider and a service provider as a prerequisite to a federated single-sign-on operation. Some federated solutions support an a priori user account creation event across domains to be used to establish these accounts, thereby satisfying a requirement that a user have an authenticatable account at both an identity provider and a service provider as a prerequisite to a federated single-sign-on operation. Although some federated solutions provide a robust set of federated user lifecycle management operations, such as user account creation, user account management, user attribute management, account suspension, and account deletion, these federated management systems do not provide a lightweight solution that is suitable for certain federation partners or for certain federated purposes.

Therefore, it would be advantageous to have methods and systems in which enterprises can provide comprehensive single-sign-on experiences to users in a federated computing environment in a lightweight manner that does not require an extensive amount of a priori processing.

## **SUMMARY OF THE INVENTION**

A method, system, apparatus, and computer program product are presented to support computing systems of different enterprises that interact within a federated computing environment. Federated single-sign-on operations can be initiated at the computing systems of federation partners on behalf of a user even though the user has not established a user account at a federation partner prior to the initiation of the single-sign-on operation. For example, an identity provider can initiate a single-sign-on operation at a service provider while attempting to obtain access to a controlled resource on behalf of a user. When the service provider recognizes that it does not have a linked user account for the user that allows a single-sign-on operation from the identity provider, the service provider creates a local user account based at least in part on information from the identity provider. The service provider

## US 7,631,346 B2

3

can also pull user attributes from the identity provider as necessary to perform the user account creation operation.

## BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, further objectives, and advantages thereof, will be best understood by reference to the following detailed description when read in conjunction with the accompanying drawings, wherein:

FIG. 1A depicts a typical network of data processing systems, each of which may implement the present invention;

FIG. 1B depicts a typical computer architecture that may be used within a data processing system in which the present invention may be implemented;

FIG. 1C depicts a data flow diagram that illustrates a typical authentication process that may be used when a client attempts to access a protected resource at a server;

FIG. 1D depicts a network diagram that illustrates a typical Web-based environment in which the present invention may be implemented;

FIG. 1E depicts a block diagram that illustrates an example of a typical online transaction that might require multiple authentication operations from a user;

FIG. 2 depicts a block diagram that illustrates the terminology of the federated environment with respect to a transaction that is initiated by a user to a first federated enterprise, which, in response, invokes actions at downstream entities within the federated environment;

FIG. 3 depicts a block diagram that illustrates the integration of pre-existing data processing systems at a given domain with some federated architecture components that may be used to support an embodiment of the present invention;

FIG. 4 depicts a block diagram that illustrates an example of a manner in which some components within a federated architecture may be used to establish trust relationships to support an implementation of the present invention;

FIG. 5 depicts a block diagram that illustrates an exemplary set of trust relationships between federated domains using trust proxies and a trust broker in accordance with an exemplary federated architecture that is able to support the present invention;

FIG. 6 depicts a block diagram that illustrates a federated environment that supports federated single-sign-on operations;

FIG. 7 depicts a block diagram that illustrates some of the components in a federated domain for implementing federated user lifecycle management functionality in order to support the present invention;

FIG. 8 depicts a dataflow diagram that shows a typical prior art HTTP-redirection-based single-sign-on operation that is initiated by a federated identity provider to obtain access to a protected resource at a federated service provider;

FIGS. 9A-9B depicts dataflow diagrams that show an HTTP-redirection-based single-sign-on operation that is initiated by a federated identity provider to obtain access to a protected resource at a federated service provider while performing a runtime linked-user-account creation operation at the federated service provider in accordance with an embodiment of the present invention;

FIGS. 9C-9E depict dataflow diagrams that show an HTTP-redirection-based single-sign-on operation that is initiated by a federated identity provider to obtain access to a protected resource at a federated service provider with alter-

4

native methods for obtaining user attributes by the federated service provider in accordance with an embodiment of the present invention;

FIG. 10 depicts a flowchart that shows a more detailed process for performing a runtime linked-user-account creation operation at a service provider during a single-sign-on operation that has been initiated by an identity provider;

FIG. 11A depicts a dataflow diagram that shows an HTTP-redirection-based pull-type single-sign-on operation that is initiated by a federated service provider to allow access to a protected resource at the federated service provider while performing a runtime linked-user-account creation operation at the federated service provider in accordance with an embodiment of the present invention; and

FIGS. 11B-11D depict a set of dataflow diagrams that show an HTTP-redirection-based pull-type single-sign-on operation that is initiated by a federated service provider to allow access to a protected resource at the federated service provider with additional retrieval of user attribute information from a federated identity provider while performing a runtime linked-user-account creation operation at the federated service provider in accordance with an embodiment of the present invention.

## DETAILED DESCRIPTION OF THE INVENTION

In general, the devices that may comprise or relate to the present invention include a wide variety of data processing technology. Therefore, as background, a typical organization of hardware and software components within a distributed data processing system is described prior to describing the present invention in more detail.

With reference now to the figures, FIG. 1A depicts a typical network of data processing systems, each of which may implement the present invention. Distributed data processing system 100 contains network 101, which is a medium that may be used to provide communications links between various devices and computers connected together within distributed data processing system 100. Network 101 may include permanent connections, such as wire or fiber optic cables, or temporary connections made through telephone or wireless communications. In the depicted example, server 102 and server 103 are connected to network 101 along with storage unit 104. In addition, clients 105-107 also are connected to network 101. Clients 105-107 and servers 102-103 may be represented by a variety of computing devices, such as mainframes, personal computers, personal digital assistants (PDAs), etc. Distributed data processing system 100 may include additional servers, clients, routers, other devices, and peer-to-peer architectures that are not shown.

In the depicted example, distributed data processing system 100 may include the Internet with network 101 representing a worldwide collection of networks and gateways that use various protocols to communicate with one another, such as LDAP (Lightweight Directory Access Protocol), TCP/IP (Transport Control Protocol/Internet Protocol), HTTP (Hypertext Transport Protocol), etc. Of course, distributed data processing system 100 may also include a number of different types of networks, such as, for example, an intranet, a local area network (LAN), or a wide area network (WAN). For example, server 102 directly supports client 109 and network 110, which incorporates wireless communication links. Network-enabled phone 111 connects to network 110 through wireless link 112, and PDA 113 connects to network 110 through wireless link 114. Phone 111 and PDA 113 can also directly transfer data between themselves across wireless link 115 using an appropriate technology, such as Bluetooth™

US 7,631,346 B2

5

wireless technology, to create so-called personal area networks or personal ad-hoc networks. In a similar manner, PDA 113 can transfer data to PDA 107 via wireless communication link 116.

The present invention could be implemented on a variety of hardware platforms and software environments. FIG. 1A is intended as an example of a heterogeneous computing environment and not as an architectural limitation for the present invention.

With reference now to FIG. 1B, a diagram depicts a typical computer architecture of a data processing system, such as those shown in FIG. 1A, in which the present invention may be implemented. Data processing system 120 contains one or more central processing units (CPUs) 122 connected to internal system bus 123, which interconnects random access memory (RAM) 124, read-only memory 126, and input/output adapter 128, which supports various I/O devices, such as printer 130, disk units 132, or other devices not shown, such as a audio output system, etc. System bus 123 also connects communication adapter 134 that provides access to communication link 136. User interface adapter 148 connects various user devices, such as keyboard 140 and mouse 142, or other devices not shown, such as a touch screen, stylus, microphone, etc. Display adapter 144 connects system bus 123 to display device 146.

Those of ordinary skill in the art will appreciate that the hardware in FIG. 1B may vary depending on the system implementation. For example, the system may have one or more processors, such as an Intel® Pentium®-based processor and a digital signal processor (DSP), and one or more types of volatile and non-volatile memory. Other peripheral devices may be used in addition to or in place of the hardware depicted in FIG. 1B. The depicted examples are not meant to imply architectural limitations with respect to the present invention.

In addition to being able to be implemented on a variety of hardware platforms, the present invention may be implemented in a variety of software environments. A typical operating system may be used to control program execution within each data processing system. For example, one device may run a Unix® operating system, while another device contains a simple Java® runtime environment. A representative computer platform may include a browser, which is a well known software application for accessing hypertext documents in a variety of formats, such as graphic files, word processing files, Extensible Markup Language (XML), Hypertext Markup Language (HTML), Handheld Device Markup Language (HDML), Wireless Markup Language (WML), and various other formats and types of files. It should also be noted that the distributed data processing system shown in FIG. 1A is contemplated as being fully able to support a variety of peer-to-peer subnets and peer-to-peer services.

With reference now to FIG. 1C, a data flow diagram illustrates a typical authentication process that may be used when a client attempts to access a protected resource at a server. As illustrated, the user at a client workstation 150 seeks access over a computer network to a protected resource on a server 151 through the user's web browser executing on the client workstation. A protected or controlled resource is a resource (an application, an object, a document, a page, a file, executable code, or other computational resource, communication-type resource, etc.) for which access is controlled or restricted. A protected resource is identified by a Uniform Resource Locator (URL), or more generally, a Uniform Resource Identifier (URI), that can only be accessed by an authenticated and/or authorized user. The computer network

6

may be the Internet, an intranet, or other network, as shown in FIG. 1A or FIG. 1B, and the server may be a web application server (WAS), a server application, a servlet process, or the like.

The process is initiated when the user requests a server-side protected resource, such as a web page within the domain "ibm.com" (step 152). The terms "server-side" and "client-side" refer to actions or entities at a server or a client, respectively, within a networked environment. The web browser (or associated application or applet) generates an HTTP request (step 153) that is sent to the web server that is hosting the domain "ibm.com". The terms "request" and "response" should be understood to comprise data formatting that is appropriate for the transfer of information that is involved in a particular operation, such as messages, communication protocol information, or other associated information.

The server determines that it does not have an active session for the client (step 154), so the server initiates and completes the establishment of an SSL (Secure Sockets Layer) session between the server and the client (step 155), which entails multiple transfers of information between the client and the server. After an SSL session is established, subsequent communication messages are transferred within the SSL session; any secret information remains secure because of the encrypted communications within the SSL session.

However, the server needs to determine the identity of the user before allowing the user to have access to protected resources, so the server requires the user to perform an authentication process by sending the client some type of authentication challenge (step 156). The authentication challenge may be in various formats, such as an HTML form. The user then provides the requested or required information (step 157), such as a username or other type of user identifier along with an associated password or other form of secret information.

The authentication response information is sent to the server (step 158), at which point the server authenticates the user or client (step 159), e.g., by retrieving previously submitted registration information and matching the presented authentication information with the user's stored information. Assuming the authentication is successful, an active session is established for the authenticated user or client. The server creates a session identifier for the client, and any subsequent request messages from the client within the session would be accompanied by the session identifier.

The server then retrieves the originally requested web page and sends an HTTP response message to the client (step 160), thereby fulfilling the user's original request for the protected resource. At that point, the user may request another page within "ibm.com" (step 161) by clicking a hypertext link within a browser window, and the browser sends another HTTP request message to the server (step 162). At that point, the server recognizes that the user has an active session (step 163) because the user's session identifier is returned to the server in the HTTP request message, and the server sends the requested web page back to the client in another HTTP response message (step 164). Although FIG. 1C depicts a typical prior art process, it should be noted that other alternative session state management techniques may be depicted, such as URL rewriting or using cookies to identify users with active sessions, which may include using the same cookie that is used to provide proof of authentication.

With reference now to FIG. 1D, a diagram illustrates a typical Web-based environment in which the present invention may be implemented. In this environment, a user of browser 170 at client 171 desires to access a protected

## US 7,631,346 B2

7

resource on web application server **172** in DNS domain **173**, or on web application server **174** in DNS domain **175**.

In a manner similar to that shown in FIG. **1C**, a user can request a protected resource at one of many domains. In contrast to FIG. **1C**, which shows only a single server at a particular domain, each domain in FIG. **1D** has multiple servers. In particular, each domain may have an associated authentication server **176** and **177**.

In this example, after client **171** issues a request for a protected resource at domain **173**, web application server **172** determines that it does not have an active session for client **171**, and it requests that authentication server **176** perform an appropriate authentication operation with client **171**. Authentication server **176** communicates the result of the authentication operation to web application server **172**. If the user (or browser **170** or client **171** on behalf of the user) is successfully authenticated, then web application server **172** establishes a session for client **171** and returns the requested protected resource. Typically, once the user is authenticated by the authentication server, a cookie may be set and stored in a cookie cache in the browser. FIG. **1D** is merely an example of one manner in which the processing resources of a domain may be shared amongst multiple servers, particularly to perform authentication operations.

In a similar manner, after client **171** issues a request for a protected resource at domain **175**, authentication server **177** performs an appropriate authentication operation with client **171**, after which web application server **174** establishes a session for client **171** and returns the requested protected resource. Hence, FIG. **1D** illustrates that client **171** may have multiple concurrent sessions in different domains yet is required to complete multiple authentication operations to establish those concurrent sessions.

With reference now to FIG. **1E**, a block diagram depicts an example of a typical online transaction that might require multiple authentication operations from a user. Referring again to FIG. **1C** and FIG. **1D**, a user may be required to complete an authentication operation prior to gaining access to a controlled resource, as shown in FIG. **1C**. Although not shown in FIG. **1C**, an authentication manager may be deployed on server **151** to retrieve and employ user information that is required to authenticate a user. As shown in FIG. **1D**, a user may have multiple current sessions within different domains **173** and **175**, and although they are not shown in FIG. **1D**, each domain may employ an authentication manager in place of or in addition to the authentication servers. In a similar manner, FIG. **1E** also depicts a set of domains, each of which support some type of authentication manager. FIG. **1E** illustrates some of the difficulties that a user may experience when accessing multiple domains that require the user to complete an authentication operation for each domain.

User **190** may be registered at ISP domain **191**, which may support authentication manager **192** that authenticates user **190** for the purpose of completing transactions with respect to domain **191**. ISP domain **191** may be an Internet Service Provider (ISP) that provides Internet connection services, email services, and possibly other e-commerce services. Alternatively, ISP domain **191** may be an Internet portal that is frequently accessed by user **190**.

Similarly, domains **193**, **195**, and **197** represent typical web service providers. Government domain **193** supports authentication manager **194** that authenticates users for completing various government-related transactions. Banking domain **195** supports authentication manager **196** that authenticates users for completing transactions with an online bank. E-commerce domain **197** supports authentication manager **198** that authenticates users for completing online purchases.

8

As noted previously, when a user attempts to move from one domain to another domain within the Internet or World Wide Web by accessing resources at the different domains, a user may be subjected to multiple user authentication requests or requirements, which can significantly slow the user's progress across a set of domains. Using FIG. **1E** as an exemplary environment, user **190** may be involved in a complicated online transaction with e-commerce domain **197** in which the user is attempting to purchase an on-line service that is limited to users who are at least 18 years old and who have a valid driver license, a valid credit card, and a U.S. bank account. This online transaction may involve domains **191**, **193**, **195**, and **197**.

Typically, a user might not maintain an identity and/or attributes within each domain that participates in a typical online transaction. In this example, user **190** may have registered his or her identity with the user's ISP, but to complete the online transaction, the user might also be required to authenticate to domains **193**, **195**, and **197**. If each of the domains does not maintain an identity for the user, then the user's online transaction may fail. Even if the user can be authenticated by each domain, it is not guaranteed that the different domains can transfer information between themselves in order to complete the user's transaction.

Given the preceding brief description of some current technology, the description of the remaining figures relates to federated computer environments in which the present invention may operate. Prior to discussing the present invention in more detail, however, some terminology is introduced.

#### Terminology

The terms "entity" or "party" generally refers to an organization, an individual, or a system that operates on behalf of an organization, an individual, or another system. The term "domain" connotes additional characteristics within a network environment, but the terms "entity", "party", and "domain" can be used interchangeably. For example, the term "domain" may also refer to a DNS (Domain Name System) domain, or more generally, to a data processing system that includes various devices and applications that appear as a logical unit to exterior entities.

The terms "request" and "response" should be understood to comprise data formatting that is appropriate for the transfer of information that is involved in a particular operation, such as messages, communication protocol information, or other associated information. A protected resource is a resource (an application, an object, a document, a page, a file, executable code, or other computational resource, communication-type resource, etc.) for which access is controlled or restricted.

A token provides direct evidence of a successful operation and is produced by the entity that performs the operation, e.g., an authentication token that is generated after a successful authentication operation. A Kerberos token is one example of an authentication token that may be used with the present invention. More information on Kerberos may be found in Kohl et al., "The Kerberos Network Authentication Service (V5)", Internet Engineering Task Force (IETF) Request for Comments (RFC) 1510, 09/1993.

An assertion provides indirect evidence of some action. Assertions may provide indirect evidence of identity, authentication, attributes, authorization decisions, or other information and/or operations. An authentication assertion provides indirect evidence of authentication by an entity that is not the authentication service but that listened to the authentication service.

A Security Assertion Markup Language (SAML) assertion is an example of a possible assertion format that may be used with the present invention. SAML has been promulgated by

US 7,631,346 B2

9

the Organization for the Advancement of Structured Information Standards (OASIS), which is a non-profit, global consortium. SAML is described in "Assertions and Protocol for the OASIS Security Assertion Markup Language (SAML)", Committee Specification 01, May 31, 2002, as follows:

The Security Assertion Markup Language (SAML) is an XML-based framework for exchanging security information. This security information is expressed in the form of assertions about subjects, where a subject is an entity (either human or computer) that has an identity in some security domain. A typical example of a subject is a person, identified by his or her email address in a particular Internet DNS domain. Assertions can convey information about authentication acts performed by subjects, attributes of subjects, and authorization decisions about whether subjects are allowed to access certain resources. Assertions are represented as XML constructs and have a nested structure, whereby a single assertion might contain several different internal statements about authentication, authorization, and attributes. Note that assertions containing authentication statements merely describe acts of authentication that happened previously. Assertions are issued by SAML authorities, namely, authentication authorities, attribute authorities, and policy decision points. SAML defines a protocol by which clients can request assertions from SAML authorities and get a response from them. This protocol, consisting of XML-based request and response message formats, can be bound to many different underlying communications and transport protocols; SAML currently defines one binding, to SOAP over HTTP. SAML authorities can use various sources of information, such as external policy stores and assertions that were received as input in requests, in creating their responses. Thus, while clients always consume assertions, SAML authorities can be both producers and consumers of assertions.

The SAML specification states that an assertion is a package of information that supplies one or more statements made by an issuer. SAML allows issuers to make three different kinds of assertion statements: authentication, in which the specified subject was authenticated by a particular means at a particular time; authorization, in which a request to allow the specified subject to access the specified resource has been granted or denied; and attribute, in which the specified subject is associated with the supplied attributes. As discussed further below, various assertion formats can be translated to other assertion formats when necessary.

Authentication is the process of validating a set of credentials that are provided by a user or on behalf of a user. Authentication is accomplished by verifying something that a user knows, something that a user has, or something that the user is, i.e. some physical characteristic about the user. Something that a user knows may include a shared secret, such as a user's password, or by verifying something that is known only to a particular user, such as a user's cryptographic key. Something that a user has may include a smartcard or hardware token. Some physical characteristic about the user might include a biometric input, such as a fingerprint or a retinal map.

An authentication credential is a set of challenge/response information that is used in various authentication protocols. For example, a username and password combination is the most familiar form of authentication credentials. Other forms of authentication credential may include various forms of challenge/response information, Public Key Infrastructure (PKI) certificates, smartcards, biometrics, etc. An authentication

10

credential is differentiated from an authentication assertion: an authentication credential is presented by a user as part of an authentication protocol sequence with an authentication server or service, and an authentication assertion is a statement about the successful presentation and validation of a user's authentication credentials, subsequently transferred between entities when necessary.

Federation Model for Computing Environment that May Incorporate the Present Invention

In the context of the World Wide Web, users are coming to expect the ability to jump from interacting with an application on one Internet domain to another application on another domain with minimal regard to the information barriers between each particular domain. Users do not want the frustration that is caused by having to authenticate to multiple domains for a single transaction. In other words, users expect that organizations should interoperate, but users generally want domains to respect their privacy. In addition, users may prefer to limit the domains that permanently store private information. These user expectations exist in a rapidly evolving heterogeneous environment in which many enterprises and organizations are promulgating competing authentication techniques.

The present invention is supported within a federation model that allows enterprises to provide a single-sign-on experience to a user. In other words, the present invention may be implemented within a federated, heterogeneous environment. As an example of a transaction that would benefit from a federated, heterogeneous environment, referring again to FIG. 1E, user 190 is able to authenticate to domain 191 and then have domain 191 provide the appropriate assertions to each downstream domain that might be involved in a transaction. These downstream domains need to be able to understand and trust authentication assertions and/or other types of assertions, even though there are no pre-established assertion formats between domain 191 and these other downstream domains. In addition to recognizing the assertions, the downstream domains need to be able to translate the identity contained within an assertion to an identity that represents user 190 within a particular domain, even though there is no pre-established identity mapping relationship. It should be noted, though, that the present invention is applicable to various types of domains and is not limited to ISP-type domains that are represented within FIG. 1E as exemplary domains.

The present invention is supported within a federated environment. In general, an enterprise has its own user registry and maintains relationships with its own set of users. Each enterprise typically has its own means of authenticating these users. However, the federated scheme for use with the present invention allows enterprises to cooperate in a collective manner such that users in one enterprise can leverage relationships with a set of enterprises through an enterprise's participation in a federation of enterprises. Users can be granted access to resources at any of the federated enterprises as if they had a direct relationship with each enterprise. Users are not required to register at each business of interest, and users are not constantly required to identify and authenticate themselves. Hence, within this federated environment, an authentication scheme allows for a single-sign-on experience within the rapidly evolving heterogeneous environments in information technology.

In the context of the present invention, a federation is a set of distinct entities, such as enterprises, organizations, institutions, etc., that cooperate to provide a single-sign-on, ease-of-use experience to a user; a federated environment differs from a typical single-sign-on environment in that two enterprises need not have a direct, pre-established, relationship

US 7,631,346 B2

11

defining how and what information to transfer about a user. Within a federated environment, entities provide services which deal with authenticating users, accepting authentication assertions, e.g., authentication tokens, that are presented by other entities, and providing some form of translation of the identity of the vouched-for user into one that is understood within the local entity.

Federation eases the administrative burden on service providers. A service provider can rely on its trust relationships with respect to the federation as a whole; the service provider does not need to manage authentication information, such as user password information, because it can rely on authentication that is accomplished by a user's authentication home domain or an identity provider.

The system that supports the present invention also concerns a federated identity management system that establishes a foundation in which loosely coupled authentication, user enrollment, user profile management and/or authorization services collaborate across security domains. Federated identity management allows services residing in disparate security domains to securely interoperate and collaborate even though there may be differences in the underlying security mechanisms and operating system platforms at these disparate domains.

#### Identity Provider vs. Service Provider

As mentioned above and as explained in more detail further below, a federated environment provides significant user benefits. A federated environment allows a user to authenticate at a first entity, which may act as an issuing party to issue an authentication assertion about the user for use at a second entity. The user can then access protected resources at a second, distinct entity, termed the relying party, by presenting the authentication assertion that was issued by the first entity without having to explicitly re-authenticate at the second entity. Information that is passed from an issuing party to a relying party is in the form of an assertion, and this assertion may contain different types of information in the form of statements. For example, an assertion may be a statement about the authenticated identity of a user, or it may be a statement about user attribute information that is associated with a particular user.

With reference now to FIG. 2, a block diagram depicts the terminology of the federated environment with respect to a transaction that is initiated by a user to a first federated enterprise, which, in response, invokes actions at downstream entities within the federated environment. FIG. 2 shows that the terminology may differ depending on the perspective of an entity within the federation for a given federated operation. More specifically, FIG. 2 illustrates that a computing environment that supports the present invention supports the transitivity of trust and the transitivity of the authentication assertion process; a domain or an entity can issue an assertion based on its trust in an identity as asserted by another domain or another entity.

User 202 initiates a transaction through a request for a protected resource at enterprise 204. If user 202 has been authenticated by enterprise 204 or will eventually be authenticated by enterprise 204 during the course of a transaction, then enterprise 204 may be termed the user's home domain for this federated session. Assuming that the transaction requires some type of operation by enterprise 206 and enterprise 204 transfers an assertion to enterprise 206, then enterprise 204 is the issuing entity with respect to the particular operation, and enterprise 206 is the relying entity for the operation.

The issuing entity issues an assertion for use by the relying domain; an issuing entity is usually, but not necessarily, the

12

user's home domain or the user's identity provider. Hence, it would usually be the case that the issuing party has authenticated the user using a typical authentication operation. However, it is possible that the issuing party has previously acted as a relying party whereby it received an assertion from a different issuing party. In other words, since a user-initiated transaction may cascade through a series of enterprises within a federated environment, a receiving party may subsequently act as an issuing party for a downstream transaction. In general, any entity that has the ability to issue authentication assertions on behalf of a user can act as an issuing entity.

The relying entity is an entity that receives an assertion from an issuing entity. The relying party is able to accept, trust, and understand an assertion that is issued by a third party on behalf of the user, i.e. the issuing entity; it is generally the relying entity's duty to use an appropriate authentication authority to interpret an authentication assertion. A relying party is an entity that relies on an assertion that is presented on behalf of a user or another entity. In this manner, a user can be given a single-sign-on experience at the relying entity instead of requiring the relying entity to prompt the user for the user's authentication credentials as part of an interactive session with the user.

Referring again to FIG. 2, assuming that the transaction requires further operations such that enterprise 206 transfers an assertion to enterprise 208, then enterprise 206 is an upstream entity that acts as the issuing entity with respect to the subsequent or secondary transaction operation, and enterprise 208 is a downstream entity that acts as the relying entity for the operation; in this case, enterprise 208 may be regarded as another downstream entity with respect to the original transaction, although the subsequent transaction can also be described with respect to only two entities.

As shown in FIG. 2, a federated entity may act as a user's home domain, which provides identity information and attribute information about federated users. An entity within a federated computing environment that provides identity information, identity or authentication assertions, or identity services may be termed an identity provider. Other entities or federation partners within the same federation may rely on an identity provider for primary management of a user's authentication credentials, e.g., accepting a single-sign-on token that is provided by the user's identity provider; a domain at which the user authenticates may be termed the user's (authentication) home domain. The identity provider may be physically supported by the user's employer, the user's ISP, or some other commercial entity.

An identity provider is a specific type of service that provides identity information as a service to other entities within a federated computing environment. With respect to most federated transactions, an issuing party for an authentication assertion would usually be an identity provider; any other entity can be distinguished from the identity provider. Any other entity that provides a service within the federated computing environment can be categorized as a service provider. Once a user has authenticated to the identity provider, other entities or enterprises in the federation may be regarded as merely service providers for the duration of a given federated session or a given federated transaction.

In some circumstances, there may be multiple entities within a federated environment that may act as identity providers for a user. For example, the user may have accounts at multiple federated domains, each of which is able to act as an identity provider for the user; these domains do not necessarily have information about the other domains nor about a user's identity at a different domain.

US 7,631,346 B2

13

Although it may be possible that there could be multiple enterprises within a federated environment that may act as identity providers, e.g., because there may be multiple enterprises that have the ability to generate and validate a user's authentication credentials, etc., a federated transaction usually involves only a single identity provider. If there is only a single federated entity that is able to authenticate a user, e.g., because there is one and only one entity within the federation with which the user has performed a federated enrollment or registration operation, then it would be expected that this entity would act as the user's identity provider in order to support the user's transactions throughout the federated environment.

Within some federated transactions that require the interoperation of multiple service providers, a downstream service provider may accept an assertion from an upstream service provider; the conditions in which an upstream service provider may act as an issuing entity to a downstream service provider that is acting as a relying party may depend upon the type of trust relationship between the service providers and the type of transaction between the service providers. Within the scope of a simple federated transaction, however, there is only one entity that acts as an issuing entity.

The present invention may be supported within a given computing environment in which a federated infrastructure can be added to existing systems while minimizing the impact on an existing, non-federated architecture. Hence, operations, including authentication operations, at any given enterprise or service provider are not necessarily altered by the fact that an entity may also participate within a federated environment. In other words, even though an entity's computing systems may be integrated into a federated environment, a user may be able to continue to perform various operations, including authentication operations, directly with an enterprise in a non-federated manner. However, the user may be able to have the same end-user experience while performing a federated operation with respect to a given entity as if the user had performed a similar operation with the given entity in a non-federated manner. Hence, it should be noted that not all of a given enterprise's users necessarily participate federated transactions when the given enterprise participates in a federation; some of the enterprise's users may interact with the enterprise's computing systems without performing any federated transactions.

Moreover, user registration within the computing environment of a given enterprise, e.g., establishment of a user account in a computer system, is not necessarily altered by the fact that the enterprise may also participate within a federated environment. For example, a user may still establish an account at a domain through a legacy or pre-existing registration process that is independent of a federated environment. Hence, in some cases, the establishment of a user account at an enterprise may or may not include the establishment of account information that is valid across a federation when the enterprise participates within a federated computing environment.

Federated Architecture—Federation Front-End for Legacy Systems

With reference now to FIG. 3, a block diagram depicts the integration of pre-existing data processing systems at a given domain with some federated architecture components that may be used to support an embodiment of the present invention. A federated environment includes federated entities that provide a variety of services for users. User 312 interacts with client device 314, which may support browser application 216 and various other client applications 318. User 312 is distinct from client device 314, browser 316, or any other

14

software that acts as interface between user and other devices and services. In some cases, the following description may make a distinction between the user acting explicitly within a client application and a client application that is acting on behalf of the user. In general, though, a requester is an intermediary, such as a client-based application, browser, SOAP client, etc., that may be assumed to act on behalf of the user.

Browser application 316 may be a typical browser, including those found on mobile devices, that comprises many modules, such as HTTP communication component 320 and markup language (ML) interpreter 322. Browser application 316 may also support plug-ins, such as web services client 324, and/or downloadable applets, which may or may not require a virtual machine runtime environment. Web services client 324 may use Simple Object Access Protocol (SOAP), which is a lightweight protocol for defining the exchange of structured and typed information in a decentralized, distributed environment. SOAP is an XML-based protocol that consists of three parts: an envelope that defines a framework for describing what is in a message and how to process it; a set of encoding rules for expressing instances of application-defined datatypes; and a convention for representing remote procedure calls and responses. User 312 may access web-based services using browser application 316, but user 312 may also access web services through other web service clients on client device 314. Some of the federated operations may employ HTTP redirection via the user's browser to exchange information between entities in a federated environment. However, it should be noted that the present invention may be supported over a variety of communication protocols and is not meant to be limited to HTTP-based communications. For example, the entities in the federated environment may communicate directly when necessary; messages are not required to be redirected through the user's browser.

The present invention may be supported in a manner such that components that are required for a federated environment can be integrated with pre-existing systems. FIG. 3 depicts one embodiment for implementing these components as a front-end to a pre-existing system. The pre-existing components at a federated domain can be considered as legacy applications or back-end processing components 330, which include authentication service runtime (ASR) servers 332 in a manner similar to that shown in FIG. 4. ASR servers 332 are responsible for authenticating users when the domain controls access to application servers 334, which can be considered to generate, retrieve, or otherwise support or process protected resources 335. The domain may continue to use legacy user registration application 336 to register users for access to application servers 334. Information that is needed to authenticate a registered user with respect to legacy operations is stored in enterprise user registry 338; enterprise user registry 338 may be accessible to federation components as well.

After joining a federated environment, the domain may continue to operate without the intervention of federated components. In other words, the domain may be configured so that users may continue to access particular application servers or other protected resources directly without going through a point-of-contact server or other component implementing this point-of-contact server functionality; a user that accesses a system in this manner would experience typical authentication flows and typical access. In doing so, however, a user that directly accesses the legacy system would not be able to establish a federated session that is known to the domain's point-of-contact server.

US 7,631,346 B2

15

The domain's legacy functionality can be integrated into a federated environment through the use of federation front-end processing **340**, which includes point-of-contact server **342** and trust proxy server **344** (or more simply, trust proxy **344** or trust service **344**) which itself interacts with Security Token Service (STS) **346**, which are described in more detail below with respect to FIG. 4. Federation configuration application **348** allows an administrative user to configure the federation front-end components to allow them to interface with the legacy back-end components through federation interface unit **350**. Federated functionality may be implemented in distinct system components or modules. In a preferred embodiment, most of the functionality for performing federation operations may be implemented by a collection of logical components within a single federation application; federated user lifecycle management application **352** includes trust service **344** along with single-sign-on protocol service (SPS) **354**. Trust service **344** may comprise identity-and-attribute service (I&AS) **356**, which is responsible for identity mapping operations, attribute retrieval, etc., as part of federation functionality. Identity-and-attribute service **356** may also be employed by single-sign-on protocol service **354** during single-sign-on operations. A federation user registry **358** may be employed in certain circumstances to maintain user-related information for federation-specific purposes.

Legacy or pre-existing authentication services at a given enterprise may use various, well known, authentication methods or tokens, such as username/password or smart card token-based information. However, in a preferred federated computing system for supporting the present invention, the functionality of a legacy authentication service can be used in a federated environment through the use of point-of-contact servers. Users may continue to access a legacy authentication server directly without going through a point-of-contact server, although a user that accesses a system in this manner would experience typical authentication flows and typical access; a user that directly accesses a legacy authentication system would not be able to generate a federated authentication assertion as proof of identity in accordance with the present invention. One of the roles of the federation front-end is to translate a federated authentication token received at a point-of-contact server into a format understood by a legacy authentication service. Hence, a user accessing the federated environment via the point-of-contact server would not necessarily be required to re-authenticate to the legacy authentication service. Preferably, the user would be authenticated to a legacy authentication service by a combination of the point-of-contact server and a trust proxy such that it appears as if the user was engaged in an authentication dialog.

Federated Architecture—Point-of-Contact Servers, Trust Proxies, and Trust Brokers

With reference now to FIG. 4, a block diagram depicts an example of a manner in which some components within a federated architecture may be used to establish trust relationships to support an implementation of the present invention. A federated environment includes federated enterprises or similar entities that provide a variety of services for users. A user, through an application on a client device, may attempt to access resources at various entities, such as enterprise **410**. A point-of-contact server at each federated enterprise, such as point-of-contact (POC) server **412** at enterprise **410**, is the entry point into the federated environment for requests from a client to access resources that are supported and made available by enterprise **410**. The point-of-contact server minimizes the impact on existing components within an existing, non-federated architecture, e.g., legacy systems, because the point-of-contact server handles many of the federation

16

requirements. The point-of-contact server provides session management, protocol conversion, and possibly initiates authentication and/or attribute assertion conversion. For example, the point-of-contact server may translate HTTP or HTTPS messages to SOAP and vice versa. As explained in more detail further below, the point-of-contact server may also be used to invoke a trust proxy to translate assertions, e.g., a SAML token received from an issuing party can be translated into a Kerberos token understood by a receiving party.

A trust service (also termed a trust proxy, a trust proxy server, or a trust service), such as trust proxy (TP) **414** at enterprise **410**, establishes and maintains a trust relationship between two entities in a federation. A trust service generally has the ability to handle authentication token format translation (through the security token service, which is described in more detail further below) from a format used by the issuing party to one understood by the receiving party.

Together, the use of a point-of-contact server and a trust service minimize the impact of implementing a federated architecture on an existing, non-federated set of systems. Hence, the exemplary federated architecture requires the implementation of at least one point-of-contact server and at least one trust service per federated entity, whether the entity is an enterprise, a domain, or other logical or physical entity. The exemplary federated architecture, though, does not necessarily require any changes to the existing, non-federated set of systems. Preferably, there is a single trust service for a given federated entity, although there may be multiple instances of a trust service component for availability purposes, or there may be multiple trust services for a variety of smaller entities within a federated entity, e.g., separate subsidiaries within an enterprise. It is possible that a given entity could belong to more than one federation, although this scenario would not necessarily require multiple trust services as a single trust service may be able to manage trust relationships within multiple federations.

One role of a trust service may be to determine or to be responsible for determining the required token type by another domain and/or the trust service in that domain. A trust service has the ability or the responsibility to handle authentication token format translation from a format used by the issuing party to one understood by the receiving party. Trust service **414** may also be responsible for any user identity translation or attribute translation that occurs for enterprise **410**, or this responsibility may be supported by a distinct identity-and-attribute service, e.g., such as identity-and-attribute service **356** as shown in FIG. 3. In addition, a trust service can support the implementation of aliases as representatives of a user identity that uniquely identify a user without providing any additional information about the user's real world identity. Furthermore, a trust proxy can issue authorization and/or session credentials for use by the point-of-contact server. However, a trust service may invoke a trust broker for assistance, as described further below. Identity translation may be required to map a user's identity and attributes as known to an issuing party to one that is meaningful to a receiving party. This translation may be invoked by either a trust service at an issuing entity, a trust service at a receiving entity, or both.

Trust service **414**, or a distinct identity-and-attribute service as mentioned above, may include (or interact with) an internalized component, shown as security token service (STS) component **416**, which will provide token translation and will invoke authentication service runtime (ASR) **418** to validate and generate tokens. The security token service provides the token issuance and validation services required by

US 7,631,346 B2

17

the trust service, which may include identity translation. The security token service therefore includes an interface to existing authentication service runtimes, or it incorporates authentication service runtimes into the service itself. Rather than being internalized within the trust service, the security token service component may also be implemented as a stand-alone component, e.g., to be invoked by the trust service, or it may be internalized within a transaction server, e.g., as part of an application server.

For example, a security token service component may receive a request to issue a Kerberos token. As part of the authentication information of the user for whom the token is to be created, the request may contain a binary token containing a username and password. The security token service component will validate the username and password against, e.g., an LDAP runtime (typical authentication) and will invoke a Kerberos KDC (Key Distribution Center) to generate a Kerberos ticket for this user. This token is returned to the trust service for use within the enterprise; however, this use may include externalizing the token for transfer to another domain in the federation.

In a manner similar to that described with respect to FIG. 1D, a user may desire to access resources at multiple enterprises within a federated environment, such as both enterprise 410 and enterprise 420. In a manner similar to that described above for enterprise 410, enterprise 420 comprises point-of-contact server 422, trust service 424, security token service (STS) 426, and authentication service runtime 428. Although the user may directly initiate separate transactions with each enterprise, the user may initiate a transaction with enterprise 410 which cascades throughout the federated environment. Enterprise 410 may require collaboration with multiple other enterprises within the federated environment, such as enterprise 420, to complete a particular transaction, even though the user may not have been aware of this necessity when the user initiated a transaction. Enterprise 420 becomes involved as a downstream entity, and enterprise 410 may present an assertion to enterprise 420 if necessary in order to further the user's federated transaction.

It may be the case that a trust service does not know how to interpret the authentication token that is received by an associated point-of-contact server and/or how to translate a given user identity and attributes. In this case, the trust service may choose to invoke functionality at a trust broker component, such as trust broker 430. A trust broker maintains relationships with individual trust proxies/services, thereby providing transitive trust between trust services. Using a trust broker allows each entity within a federated environment, such as enterprises 410 and 420, to establish a trust relationship with the trust broker rather than establishing multiple individual trust relationships with each entity in the federated environment. For example, when enterprise 420 becomes involved as a downstream entity for a transaction initiated by a user at enterprise 410, trust service 414 at enterprise 410 can be assured that trust service 424 at enterprise 420 can understand an assertion from trust service 414 by invoking assistance at trust broker 430 if necessary. Although FIG. 4 depicts the federated environment with a single trust broker, a federated environment may have multiple trust brokers.

It should be noted that although FIG. 4 depicts point-of-contact server 412, trust service 414, security token service component 416, and authentication service runtime 418 as distinct entities, it is not necessary for these components to be implemented on separate components. For example, it is possible for the functionality of these separate components to be implemented as a single application, as applications on a single physical device, or as distributed applications on mul-

18

multiple physical devices. In addition, FIG. 4 depicts a single point-of-contact server, a single trust service, and a single security token server for an enterprise, but an alternative configuration may include multiple point-of-contact servers, multiple trust services, and multiple security token servers for each enterprise. The point-of-contact server, the trust service, the security token service, and other federated entities may be implemented in various forms, such as software applications, objects, modules, software libraries, etc.

A trust service/STS may be capable of accepting and validating many different authentication credentials, including traditional credentials such as a username and password combinations and Kerberos tickets, and federated authentication token formats, including authentication tokens produced by a third party. A trust service/STS may allow the acceptance of an authentication token as proof of authentication elsewhere. The authentication token is produced by an issuing party and is used to indicate that a user has already authenticated to that issuing party. The issuing party produces the authentication token as a means of asserting the authenticated identity of a user. A trust service/STS is also able to process attribute tokens or tokens that are used to secure communication sessions or conversations, e.g., those that are used to manage session information in a manner similar to an SSL session identifier.

A security token service invokes an authentication service runtime as necessary. The authentication service runtime supports an authentication service capable of authenticating a user. The authentication service acts as an authentication authority that provides indications of successful or failed authentication attempts via authentication responses. The trust service/STS may internalize an authentication service, e.g., a scenario in which there is a brand-new installation of a web service that does not need to interact with an existing legacy infrastructure. Otherwise, the security token service component will invoke external authentication services for validation of authentication tokens. For example, the security token service component could "unpack" a binary token containing a username/password and then use an LDAP service to access a user registry to validate the presented credentials.

When used by another component such as an application server, the security token service component can be used to produce tokens required for single-sign-on to legacy authentication systems; this functionality may be combined with or replaced by functionality within a single-sign-on protocol service, such as SPS 354 that is shown in FIG. 3. Hence, the security token service component can be used for token translation for internal purposes, i.e. within an enterprise, and for external purposes, i.e. across enterprises in a federation. As an example of an internal purpose, a Web application server may interface to a mainframe via an IBM CICS (Customer Information Control System) transaction gateway; CICS is a family of application servers and connectors that provides enterprise-level online transaction management and connectivity for mission-critical applications. The Web application server may invoke the security token service component to translate a Kerberos ticket (as used internally by the Web application server) to an IBM RACF® passticket required by the CICS transaction gateway.

The entities that are shown in FIG. 4 can be explained using the terminology that was introduced above, e.g., "identity provider" and "service provider". As part of establishing and maintaining trust relationships, an identity provider's trust service can determine what token types are required/accepted by a service provider's trust service. Thus, trust services use this information when invoking token services from a security token service. When an identity provider's trust service is

US 7,631,346 B2

19

required to produce an authentication assertion for a service provider, the trust service determines the required token type and requests the appropriate token from the security token service.

When a service provider's trust service receives an authentication assertion from an identity provider, the trust service knows what type of assertion that it expected and what type of assertion that it needs for internal use within the service provider. The service provider's trust service therefore requests that the security token service generate the required internal-use token based on the token in the received authentication assertion.

Both trust services and trust brokers have the ability to translate an assertion received from an identity provider into a format that is understood by a service provider. The trust broker has the ability to interpret the assertion format (or formats) for each of the trust services with whom there is a direct trust relationship, thereby allowing the trust broker to provide assertion translation between an identity provider and a service provider. This translation can be requested by either party through its local trust service. Thus, the identity provider's trust service can request translation of an assertion before it is sent to the service provider. Likewise, the service provider's trust service can request translation of an assertion received from an identity provider.

Assertion translation comprises user identity translation, authentication assertion translation, attribute assertion translation, or other forms of assertion translation. Reiterating the point above, assertion translation is handled by the trust components within a federation, e.g., trust services and trust brokers. A trust service may perform the translation locally, either at the identity provider or at the service provider, or a trust service may invoke assistance from a trust broker.

Assuming that an identity provider and a service provider already have individual trust relationships with a trust broker, the trust broker can dynamically create, i.e. broker, new trust relationships between issuing parties and relying parties if necessary. After the initial trust relationship brokering operation that is provided by the trust broker, the identity provider and the service provider may directly maintain the relationship so that the trust broker need not be invoked for future translation requirements. It should be noted that translation of authentication tokens can happen at three possible places: the identity provider's trust service, the service provider's trust service, and the trust broker. Preferably, the identity provider's trust service generates an authentication assertion that is understood by the trust broker to send to the service provider. The service provider then requests a translation of this token from the trust broker into a format recognizable by the service provider. Token translation may occur before transmission, after transmission, or both before and after transmission of the authentication assertion.

#### Trust Relationships within Federated Architecture

Within an exemplary federated environment that is able to support the present invention, there are two types of "trust domains" that must be managed: enterprise trust domains and federation trust domains. The differences between these two types of trust domain are based in part on the business agreements governing the trust relationships with the trust domain and the technology used to establish trust. An enterprise trust domain contains those components that are managed by the enterprise; all components within that trust domain may implicitly trust each other. In general, there are no business agreements required to establish trust within an enterprise because the deployed technology creates inherent trust within an enterprise, e.g., by requiring mutually authenticated SSL sessions between components or by placing components

20

within a single, tightly controlled data center such that physical control and proximity demonstrate implicit trust. Referring to FIG. 2B, the legacy applications and back-end processing systems may represent an enterprise trust domain, wherein the components communicate on a secure internal network.

Federation trust domains are those that cross enterprise boundaries; from one perspective, a federation trust domain may represent trust relationships between distinct enterprise trust domains. Federation trust domains are established through trust proxies across enterprise boundaries between federation partners. Trust relationships involve some sort of a bootstrapping process by which initial trust is established between trust proxies. Part of this bootstrap process may include the establishment of shared secret keys and rules that define the expected and/or allowed token types and identifier translations. In general, this bootstrapping process can be implemented out-of-band as this process may also include the establishment of business agreements that govern an enterprise's participation in a federation and the liabilities associated with this participation.

There are a number of possible mechanisms for establishing trust in a federated business model. In a federation model, a fundamental notion of trust between the federation participants is required for business reasons in order to provide a level of assurance that the assertions (including tokens and attribute information) that are transferred between the participants are valid. If there is no trust relationship, then the service provider cannot depend upon the assertions received from the identity provider; they cannot be used by the service provider to determine how to interpret any information received from the identity provider.

For example, a large corporation may want to link several thousand global customers, and the corporation could use non-federated solutions. As a first example, the corporation could require global customers to use a digital certificate from a commercial certificate authority to establish mutual trust. The commercial certificate authority enables the servers at the corporation to trust servers located at each of the global customers. As a second example, the corporation could implement third-party trust using Kerberos; the corporation and its global customers could implement a trusted third-party Kerberos domain service that implements shared-secret-based trust. As a third example, the corporation could establish a private scheme with a proprietary security message token that is mutually trusted by the servers of its global customers.

Any one of these approaches may be acceptable if the corporation needed to manage trust relationships with a small number of global customers, but this may become unmanageable if there are hundreds or thousands of potential federation partners. For example, while it may be possible for the corporation to force its smaller partners to implement a private scheme, it is unlikely that the corporation will be able to impose many requirements on its larger partners.

An enterprise may employ trust relationships established and maintained through trust proxies and possibly trust brokers. An advantage of the exemplary federated architecture that is shown in the figures is that it does not impose additional requirements above and beyond the current infrastructures of an enterprise and its potential federation partners.

However, this exemplary federation architecture does not relieve an enterprise and its potential federation partners from the preliminary work required to establish business and liability agreements that are required for participation in the federation. In addition, the participants cannot ignore the technological bootstrapping of a trust relationship. The

US 7,631,346 B2

21

exemplary federation architecture allows this bootstrapping to be flexible, e.g., a first federation partner can issue a Kerberos ticket with certain information, while a second federation partner can issue a SAML authentication assertion with certain information.

In the exemplary federation architecture, the trust relationships are managed by the trust proxies, which may include (or may interact with) a security token service that validates and translates a token that is received from an identity provider based on the pre-established relationship between two trust proxies. In situations where it is not feasible for a federated enterprise to establish trust relationships (and token translation) with another federated enterprise, a trust broker may be invoked; however, the federated enterprise would need to establish a relationship with a trust broker.

With reference now to FIG. 5, a block diagram depicts an exemplary set of trust relationships between federated domains using trust proxies and a trust broker in accordance with an exemplary federated architecture that is able to support the present invention. Although FIG. 4 introduced the trust broker, FIG. 5 illustrates the importance of transitive trust relationships within the exemplary federated architecture.

Federated domains 502-506 incorporate trust proxies 508-512, respectively. Trust proxy 508 has direct trust relationship 514 with trust proxy 510. Trust broker 520 has direct trust relationship 516 with trust proxy 510, and trust broker 520 has direct trust relationship 518 with trust proxy 512. Trust broker 520 is used to establish, on behalf of a federation participant, a trust relationship based on transitive trust with other federation partners. The principle of transitive trust allows trust proxy 510 and trust proxy 512 to have brokered trust relationship 522 via trust broker 520. Neither trust proxy 510 nor 512 need to know how to translate or validate the other's assertions; the trust broker may be invoked to translate an assertion into one that is valid, trusted, and understood at the other trust proxy.

Business agreements that specify contractual obligations and liabilities with respect to the trust relationships between federated enterprises can be expressed in XML through the use of the ebXML (Electronic Business using XML) standards. For example, a direct trust relationship could be represented in an ebXML document; each federated domain that shares a direct trust relationship would have a copy of a contract that is expressed as an ebXML document. Operational characteristics for various entities within a federation may be specified within ebXML choreographies and published within ebXML registries; any enterprise that wishes to participate in a particular federation, e.g., to operate a trust proxy or trust broker, would need to conform to the published requirements that were specified by that particular federation for all trust proxies or trust brokers within the federation. A security token service could parse these ebXML documents for operational details on the manner in which tokens from other domains are to be translated. It should be noted, though, that other standards and mechanisms could be employed to support the present invention for specifying the details about the manner in which the trust relationships within a federation are implemented.

#### Single-Sign-on within Federated Architecture

During a given user's session, the user may visit many federated domains to use the web services that are offered by those domains. Domains can publish descriptions of services that they provide using standard specifications such as UDDI and WSDL, both of which use XML as a common data format. The user finds the available services and service providers through applications that also adhere to these standard

22

specifications. SOAP provides a paradigm for communicating requests and responses that are expressed in XML. Entities within a federated environment may employ these standards among others.

Within a federation, a user expects to have a single-sign-on experience in which the user completes a single authentication operation, and this authentication operation suffices for the duration of the user's session, regardless of the federation partners visited during that session. A session can be defined as the set of transactions from (and including) the initial user authentication, i.e. logon, to logout. Within a session, a user's actions will be governed in part by the privileges granted to the user for that session.

The federated architecture that is described hereinabove supports single-sign-on operations. To facilitate a single-sign-on experience, web services that support the federated environment will also support using an authentication assertion or security token generated by a third-party to provide proof of authentication of a user. This assertion will contain some sort of evidence of the user's successful authentication to the issuing party together with an identifier for that user. For example, a user may complete traditional authentication operation with one federation partner, e.g., by providing a username and password that the federation partners uses to build authentication credentials for the user, and then the federation partner is able to provide a SAML authentication assertion that is generated by the authenticating/issuing party to a different federation partner.

The federated environment also allows web services or other applications to request web services, and these web services would also be authenticated. Authentication in a web services environment is the act of verifying the claimed identity of the web services request so that the enterprise can restrict access to authorized clients. A user who requests or invokes a web service would almost always be authenticated, so the need for authentication within a federated environment that supports the present invention is not any different from current requirements of web services for user authentication.

Authentication of users that are accessing the computational resources of an enterprise without participating in a federated session are not impacted by the presence of a federated infrastructure. For example, an existing user who authenticates with a forms-based authentication mechanism over HTTP/S to access non-federated resources at a particular domain is not affected by the introduction of support at the domain for the federated environment. Authentication is handled in part by a point-of-contact server, which in turn may invoke a separate trust proxy or trust service component; the use of a point-of-contact server minimizes the impact on the infrastructure of an existing domain. For example, the point-of-contact server can be configured to pass through all non-federated requests to be handled by the back-end or legacy applications and systems at the domain.

The point-of-contact server may choose to invoke an HTTP-based authentication method, such as basic authentication, forms-based authentication, or some other authentication method. The point-of-contact server also supports a federation domain by recognizing an assertion that has been presented by the user as proof of authentication, such as an SAML authentication assertion, wherein the assertion has crossed between enterprise domains. The point-of-contact server may invoke the trust service, which in turn may invoke its security token service for validation of authentication credentials/security tokens.

Authentication of web services or other applications comprises the same process as authentication of users. Requests from web services carry a security token containing an

US 7,631,346 B2

23

authentication assertion, and this security token would be validated by the trust service in the same manner as a token presented by a user. A request from a web service should be accompanied by this token because the web service would have discovered what authentication assertions/security tokens were required by the requested service as advertised in UDDI.

With reference now to FIG. 6, a block diagram depicts a federated environment that supports federated single-sign-on operations. User 600, through a client device and an appropriate client application, such as a browser, desires to access a web service that is provided by enterprise/domain 610, which supports data processing systems that act as a federated domain within a federated environment. Domain 610 supports point-of-contact server 612 and trust proxy or trust service 614; similarly, domain 620 supports point-of-contact server 622 and trust proxy or trust service 624, while domain 630 supports point-of-contact server 632 and trust proxy or trust service 634. The trust proxies/services rely upon trust broker 650 for assistance, as described above. Additional domains and trust proxies/services may participate in the federated environment. FIG. 6 is used to describe a federated single-sign-on operation between domain 610 and domain 620; a similar operation may occur between domain 610 and domain 630.

The user completes an authentication operation with respect to domain 610; this authentication operation is handled by point-of-contact server 612. The authentication operation is triggered when the user requests access to some resource that requires an authenticated identity, e.g., for access control purposes or for personalization purposes. Point-of-contact server 612 may invoke a legacy authentication service, or it may invoke trust proxy 614 to validate the user's presented authentication credentials. Domain 610 becomes the user's identity provider or home domain for the duration of the user's federated session.

At some later point in time, the user initiates a transaction at a federation partner, such as enterprise 620 that also supports a federated domain, thereby triggering a federated single-sign-on operation. For example, a user may initiate a new transaction at domain 620, or the user's original transaction may cascade into one or more additional transactions at other domains. As another example, the user may invoke a federated single-sign-on operation to a resource in domain 620 via point-of-contact server 612, e.g., by selecting a special link on a web page that is hosted within domain 610 or by requesting a portal page that is hosted within domain 610 but that displays resources hosted in domain 620. Point-of-contact server 612 sends a request to trust proxy 614 to generate a federation single-sign-on token for the user that is formatted to be understood or trusted by domain 620. Trust proxy 614 returns this token to point-of-contact server 612, which sends this token to point-of-contact server 622 in domain 620. Domain 610 acts as an issuing party for the user at domain 620, which acts as a relying party. The user's token would be transferred with the user's request to domain 620; this token may be sent using HTTP redirection via the user's browser, or it may be sent by invoking the request directly of point-of-contact server 622 (over HTTP or SOAP-over-HTTP) on behalf of the user identified in the token supplied by trust proxy 614.

Point-of-contact server 622 receives the request together with the federation single-sign-on token and invokes trust proxy 624. Trust proxy 624 receives the federation single-sign-on token, validates the token, and assuming that the token is valid and trusted, generates a locally valid token for the user. Trust proxy 624 returns the locally valid token to point-of-contact server 622, which establishes a session for

24

the user within domain 620. If necessary, point-of-contact server 622 can initiate a federated single-sign-on at another federated partner.

Validation of the token at domain 620 is handled by the trust proxy 624, possibly with assistance from a security token service. Depending on the type of token presented by domain 610, the security token service may need to access a user registry at domain 620. For example, domain 620 may provide a binary security token containing the user's name and password to be validated against the user registry at domain 620. Hence, in this example, an enterprise simply validates the security token from a federated partner. The trust relationship between domains 610 and 620 ensures that domain 620 can understand and trust the security token presented by domain 610 on behalf of the user.

Federated single-sign-on requires not only the validation of the security token that is presented to a relying domain on behalf of the user but the determination of a locally valid user identifier at the relying domain based on information contained in the security token. One result of a direct trust relationship and the business agreements required to establish such a relationship is that at least one party, either the issuing domain or the relying domain or both, will know how to translate the information provided by the issuing domain into an identifier valid at the relying domain. In the brief example above, it was assumed that the issuing domain, i.e. domain 610, is able to provide the relying domain, i.e. domain 620, with a user identifier that is valid in domain 620. In that scenario, the relying domain did not need to invoke any identity mapping functionality. Trust proxy 624 at domain 620 will generate a security token for the user that will "vouch-for" this user. The types of tokens that are accepted, the signatures that are required on tokens, and other requirements are all pre-established as part of the federation's business agreements. The rules and algorithms that govern identifier translation are also pre-established as part of the federation's business agreements. In the case of a direct trust relationship between two participants, the identifier translation algorithms will have been established for those two parties and may not be relevant for any other parties in the federation.

However, it is not always the case that the issuing domain will know how to map the user from a local identifier for domain 610 to a local identifier for domain 620. In some cases, it may be the relying domain that knows how to do this mapping, while in yet other cases, neither party will know how to do this translation, in which case a third party trust broker may need to be invoked. In other words, in the case of a brokered trust relationship, the issuing and relying domains do not have a direct trust relationship with each other. They will, however, have a direct trust relationship with a trust broker, such as trust broker 650. Identifier mapping rules and algorithms will have been established as part of this relationship, and the trust broker will use this information to assist in the identifier translation that is required for a brokered trust relationship.

Domain 620 receives the token that is issued by domain 610 at point-of-contact server 622, which invokes trust proxy 624 to validate the token and perform identity mapping. In this case, since trust proxy 624 is not able to map the user from a local identifier for domain 610 to a local identifier for domain 620, trust proxy 624 invokes trust broker 650, which validates the token and performs the identifier mapping. After obtaining the local identifier for the user, trust proxy 624, possibly through its security token service, can generate any local tokens that are required by the back-end applications at domain 620, e.g., a Kerberos token may be required to facilitate single-sign-on from the point-of-contact server to the

US 7,631,346 B2

25

application server. After obtaining a locally valid token, if required, the point-of-contact server is able to build a local session for the user. The point-of-contact server will also handle coarse-grained authorization of user requests and forward the authorized requests to the appropriate application servers within domain 620.

#### Federated User Lifecycle Management

A portion of the above description of FIGS. 2-6 explained an organization of components that may be used in a federated environment while other portions explained the processes for supporting single-sign-on operations across the federated environment. Service providers or relying domains within a federated environment do not necessarily have to manage a user's authentication credentials, and those relying domains can leverage a single single-sign-on token that is provided by the user's identity provider or home domain. The description of FIGS. 2-6 above, though, does not explain an explicit process by which federated user lifecycle management may be accomplished in an advantageous manner at the federated domains of federation partners.

Federated user lifecycle management functionality/service comprises functions for supporting or managing federated operations with respect to the particular user accounts or user profiles of a given user at multiple federated domains; in some cases, the functions or operations are limited to a given federated session for the user. In other words, federated user lifecycle management functionality refers to the functions that allow management of federated operations across a plurality of federated partners, possibly only during the lifecycle of a single user session within a federated computing environment.

Each federated domain might manage a user account, a user profile, or a user session of some kind with respect to the functions at each respective federated domain. For example, a particular federated domain might not manage a local user account or user profile within the particular federated domain, but the federated domain might manage a local user session for a federated transaction after the successful completion of a single-sign-on operation at the federated domain. As part of the federated user lifecycle management functionality that is supported by that particular federated domain, the federated domain can participate in a single-sign-off operation that allows the federated domain to terminate the local user session after the federated transaction is complete, thereby improving security and promoting efficient use of resources.

In another example of the use of federated user lifecycle management functionality, a user may engage in an online transaction that requires the participation of multiple federated domains. A federated domain might locally manage a user profile in order to tailor the user's experience with respect to the federated domain during each of the user's federated sessions that involve the federated domain. As part of the federated user lifecycle management functionality that is supported by that particular federated domain, the information in the federated domain's local user profile can be used in a seamless manner during a given federated transaction with information from other profiles at other federated domains that are participating in the given federated transaction. For example, the information from the user's multiple local user profiles might be combined in some type of merging operation such that the user's information is visually presented to the user, e.g., within a web page, in a manner such that the user is not aware of the different origins or sources of the user's information.

Federated user lifecycle management functionality may also comprise functions for account linking/delinking. A user is provided with a common unique user identifier across

26

federation partners, which enables single-sign-on and the retrieval of attributes (if necessary) about a user as part of the fulfillment of a request at one federation partner. Furthermore, the federation partner can request additional attributes from an identity provider using the common unique user identifier to refer to the user in an anonymous manner.

With reference now to FIG. 7, a block diagram depicts some of the components in a federated domain for implementing federated user lifecycle management functionality in order to support the present invention. FIG. 7 depicts elements at a single federated domain, such as the federated domain that is shown in FIG. 3. Some of the elements in FIG. 7 are similar or identical to elements that have been discussed hereinabove with respect to other figures, such as FIG. 3: point-of-contact server/service 702 is equivalent to point-of-contact server 342; application servers 704, which run services that control access to protected resources, are equivalent to application servers 334; protected or controlled resources 706 are equivalent to protected resources 335; and federated user lifecycle management (FULM) application 708 is equivalent to federated user lifecycle management application 352. Although firewalls were not illustrated within FIG. 3, firewalls are illustrated within FIG. 7. Firewall 710 and firewall 712 create an external DMZ (electronic DeMilitarized Zone) that protects the enterprise's computing environment from computing threats outside of the enterprise's domain, e.g., via the Internet.

The different perspectives that are shown in FIG. 3 and FIG. 7 are not incompatible or at cross-purposes. In contrast with the example that is shown in FIG. 7, FIG. 3 does not illustrate the firewalls, yet point-of-contact server 342 resides within federation front-end 340; in addition, federated user lifecycle management application 352 is contained within federation front-end 340. In FIG. 7, point-of-contact server 702 is illustrated as residing within the DMZ between firewalls 710 and 712, which form an electronic or physical front-end to the enterprise domain; in addition, federated user lifecycle management application/service 708 resides electronically behind firewall 712. Trust service 714, single-sign-on protocol service 716, and identity-and-attribute service 718 employ enterprise user registry 720 and federation user registry 722 as necessary. The different perspectives of FIG. 3 and FIG. 7 can be reconciled by regarding federation front-end 340 and back-end 330 in FIG. 3 as a logical organization of components while regarding the DMZ and the other components in FIG. 7 as forming a physical or electronic front-end and a physical or electronic back-end, either of which may contain federated components.

Reiterating the roles of a point-of-contact entity/service, the point-of-contact entity provides session management, at least with respect to a user's interaction with the federation functionality with an enterprise's computing environment; applications within a legacy back-end of the enterprise's computing environment may also implement its own session management functionality. Assuming that an enterprise implements policy functionality with respect to the federated computing environment, the point-of-contact entity may act as a policy enforcement point to some other federation partner's policy decision point. In addition, assuming that it is permissible given the implementation of the federation functionality, the point-of-contact entity is responsible for initiating a direction authentication operation against a user in those scenarios in which a single-sign-on operation is not employed. As such, the point-of-contact entity may be implemented in a variety of forms, e.g., as a reverse proxy server, as a web server plug-in, or in some other manner. The point-of-contact functionality may also be implemented within an

US 7,631,346 B2

27

application server itself, in which case the federated user lifecycle management services may be logically located within the DMZ.

More importantly, referring again to FIG. 7, federated user lifecycle management application 708 also comprises support for interfacing to, interacting with, or otherwise interoperating with federated user lifecycle management plug-ins 724, which are not shown in FIG. 3. In the exemplary architecture that is shown in FIG. 7, federated protocol runtime plug-ins provide the functionality for various types of independently published or developed federated user lifecycle management standards or profiles, such as: WS-Federation Passive Client; and Liberty Alliance ID-FF Single Sign On (B/A, B/P and LECP), Register Name Identifier, Federation Termination Notification, and Single Logout. Different sets of federated protocols may be accessed at different URI's. This approach allows the federated user lifecycle management application to concurrently support multiple standards or specifications of federated user lifecycle management, e.g., the WS-Federation web services specification versus the Liberty Alliance's specifications, within a single application, thereby minimizing the configuration impact on the overall environment for supporting different federation protocols.

More specifically, the appropriate federated user lifecycle management functionality is invoked by the point-of-contact server by redirecting and/or forwarding user requests to the federated user lifecycle management application as appropriate. Referring again to FIG. 7, point-of-contact server 702 receives user requests 730, which are then analyzed to determine the type of request that has been received, which might be indicated by the type of request message that has been received or, as noted above, by determining the destination URI within the request message. While requests 732 for protected resources continue to be forwarded to application servers 704, requests 734 for federated user lifecycle management functions, e.g., requests to invoke a single-sign-off operation, are forwarded to federated user lifecycle management application 708, which invokes the appropriate federated user lifecycle management plug-in as necessary to fulfill the received request. When a new federation protocol or a new federated function is defined, or when an existing one is somehow modified or refined, support can be added simply by plugging a new support module or can be refined by modifying a previously installed plug-in.

The exemplary implementation of a federated user lifecycle management application in FIG. 7 illustrates that the federated user lifecycle management application is able to support multiple, simultaneous, federated user lifecycle management functions while providing a pluggability feature, thereby allowing new functionality to be added to the federated user lifecycle management application in the form of a plug-in when needed without requiring any changes to the existing infrastructure. For example, assuming that the present invention is implemented using a Java™-based federated user lifecycle management application, support for a new federation protocol, such as a newly published single-sign-on protocol, can be added by configuring newly developed Java™ classes to the Java™ CLASSPATH of the federated user lifecycle management application, wherein these new classes support the new standard along with the protocol interface for supporting the present invention.

The exemplary federated architecture leverages the existing environment in which a federated user lifecycle management solution is to be integrated. The federated user lifecycle management application can be easily modified to support new protocols/standards as they evolve with minimal changes to the overall infrastructure. Any changes that might be

28

required to support new federated user lifecycle management functionality are located almost exclusively within the federated user lifecycle management application, which would require configuring the federated user lifecycle management application to understand the added functionality.

There may be minimal configuration changes in other federated components, e.g., at a point-of-contact server, in order to allow the overall infrastructure to be able to invoke new federated user lifecycle management functionality while continuing to support existing federated user lifecycle management functionality. However, the federated user lifecycle management applications are functionally independent from the remainder of the federated components in that the federated user lifecycle management applications may require only minimal interaction with other federated components of the federated environment. For example, in an exemplary embodiment, the federated user lifecycle management functionality may integrate with an enterprise-based datastore, e.g., an LDAP datastore, if federated user lifecycle management information, such as NameIdentifier values in accordance with the Liberty Alliance profiles, are to be stored in an externally-accessible federated user lifecycle management datastore as opposed to a private, internal, federated user lifecycle management datastore that is not apparent or accessible to external entities.

Hence, an existing environment needs minimal modifications to support federated user lifecycle management functionality. Moreover, changes to federated user lifecycle management functionality, including the addition of new functionality, have minimal impact on an existing federated environment. Thus, when a new single-sign-on standard is published, support for this standard is easily added.

Traditional user authentication involves interaction between an enterprise's computing environment and the end-user only; the manner in which the enterprise chooses to implement this authentication interchange is the choice of the enterprise, which has no impact on any other enterprise. When federation or cross-domain single-sign-on functionality is desired to be supported, however, it becomes a requirement that enterprise partners interact with each other. This requirement cannot be done scalably using proprietary protocols. Although adding support for standards-based federation protocols directly to a point-of-contact entity seems like a robust solution, the point-of-contact entity, which is already an existing component within the enterprise's computing environment, must be modified; moreover, it must be modified every time that one of these public federation protocols changes. Moving this functionality out of the point-of-contact entity provides a more modular approach, wherein this pluggable functionality makes it easy to maintain migrations or updates to these protocols.

#### Runtime Linked-User-Account Creation During a Single-Sign-On Operation

With reference now to FIG. 8, a dataflow diagram depicts a typical prior art HTTP-redirection-based single-sign-on operation that is initiated by a federated identity provider to obtain access to a protected resource at a federated service provider. Although the processes that are illustrated within FIG. 8 and the subsequent figures employ HTTP-based communications, the present invention is not limited to HTTP-based communications, and other communication protocols may be employed; in particular, the present invention is not limited to front-channel communications as represented by HTTP redirection-based techniques but may be equally applied to back-channel techniques, such as SOAP/HTTP or SOAP/MQ. In the dataflow in FIG. 8, the user of a client, also known as a user agent, such as a web browser application, has

US 7,631,346 B2

29

already established a user account not only at the identity provider but also at the service provider (step 802) and that the user has already authenticated to the identity provider (step 804).

One of the prerequisites for the exemplary dataflow in FIG. 8 is that, at a minimum, that the user already has a federated account with the service provider; in other words, the service provider is required to recognize user identity information for the user when it receives this information from an identity provider in order to perform a single-sign-on operation for the user when initiated by an identity provider. With step 804, the prerequisite is simply that the user has authenticated to the identity provider at some previous point in time and currently has a valid session with the identity provider; there are no requirements on the reasons for which a session was established at step 804. It should be noted that other scenarios are possible, e.g., in which the identity provider determines at some later point in time after some interaction with the user that the identity provider only performs certain operations for authenticated users. It should also be noted that other scenarios for initiating a single-sign-on process are possible; for example, a user could initiate a single-sign-on operation by requesting a protected resource at the service provider, e.g., by using a bookmarked URL within a browser application.

The single-sign-on process commences at the identity provider by sending to the client from the identity provider an offer to provide access to federated resources (step 806); the offer may be in the form of hyperlinks to resources at federated web sites or, more generally, at federated domains, and the offer may be made in the form of an HTTP response message in response to a previous HTTP request message from the client (not shown) to view a particular web page on the identity provider's web site. The user then selects one of the offered federated resources at service providers that are known to the identity provider (step 808); the selection may be facilitated by an HTTP request message from the client to the identity provider.

The identity provider builds a message for requesting access to the selected federated resource on behalf of the user such that the message also includes a single-sign-on request (step 810), and the identity provider sends the resource request with the single-sign-on request to the client (step 812), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). The redirect message redirects the client to the appropriate location, e.g., as identified by a URI within the "Location" header of the redirect message, that identifies the appropriate service at the service provider that controls access to the requested federated resource.

It should be noted that, in the prior art, a preferred manner of initiating a push-type single-sign-on operation is to include the single sign-on assertion information in a request initiated by the identity provider and sent to the service provider in response to a request triggered directly at the service provider. For example, in a computing environment that implements a single-sign-on operation as specified in the Liberty Alliance ID-FF 1.2 specifications, an AuthnResponse is built. In some scenarios, it is required that the identity provider redirect the client to a trigger URL at the service provider, whereafter the trigger URL will cause the service provider to build a message, e.g., an AuthnRequest message within the Liberty Alliance specifications, that is redirected to the identity provider, which in turn causes the identity provider to build response, e.g., an AuthnResponse; this is the means by which a push-based SSO is implemented with Liberty ID-FF 1.1.

The outgoing request message may comprise two distinct requests: one requested operation for a single-sign-on opera-

30

tion on behalf of the user of the client, and another requested operation for accessing the protected resource that has been selected by the user of the client. Alternatively, the request to access the federated resource may include an implicit request to perform a single-sign-on operation for the user such that the single-sign-on process is merely part of a larger process for accessing the selected resource. The manner in which information is provided for the requested single-sign-on operation may vary. For example, the "Location" HTTP header of the redirect message may also include a query component, e.g., appended to a URI and demarcated within the URI with a "?" character, that contains various information, including security tokens for accomplishing the single-sign-on operation.

In response to receiving the redirect message from the identity provider, the client sends an HTTP Get message to the appropriate service at the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 814). In this manner, the client accesses the appropriate service at the service provider because the URI in the HTTP Get message still contains the attached information that is required by the service at the service provider.

The service provider receives the request message from the client, and assuming that the single-sign-on aspect of the request is successfully completed (step 816) such that the user has an active session at the service provider, the service provider then processes the resource access aspect of the request message (step 818). After processing the request message, the service provider responds by sending an HTTP response message to the client (step 820), thereby concluding the process.

With reference now to FIGS. 9A-9B, dataflow diagrams depict an HTTP-redirectation-based single-sign-on operation that is initiated by a federated identity provider to obtain access to a protected resource at a federated service provider while performing a runtime linked-user-account creation operation at the federated service provider in accordance with an embodiment of the present invention. In a manner similar to that shown in FIG. 8, both FIGS. 9A-9B depict a process by which an identity provider may request a single-sign-on operation at a selected service provider. However, whereas FIG. 8 depicts only a generalized single-sign-on operation at step 816, the processes that are shown in FIGS. 9A-9B differs from the process that is shown in FIG. 8 with respect to the single-sign-on operation. Unlike the process that is shown in FIG. 8, there is no prerequisite to the processes that are shown in FIGS. 9A-9B that the user of a client has already established a user account at the service provider.

More specifically, prior art solutions for single-sign-on operations have certain prerequisites, namely that the service provider and the identity provider must both recognize the user, and they must have an agreed-upon means of referring to this user, i.e. an alias identifier, or more simply, an alias; both prerequisites must be true before the initiation of a single-sign-on operation in order for the single-sign-on operation to be successful, otherwise it would fail. In these prior art solutions, the alias is included in the single-sign-on response that is sent from the identity provider to the service provider and used by the service provider to identify the user and build a session for the user. These prerequisites exist within prior art solutions whether: (a) the single-sign-on operation is triggered by the service provider, e.g., when a user accesses a protected resource that is hosted at the service provider and the service provider needs a session for the user, thereby initiating a single-sign-on operation by sending a request to an identity provider; or (b) the single-sign-on operation is triggered by the identity provider, e.g., when an identity provider has a list of linked resources that are hosted by related

US 7,631,346 B2

31

service providers, and after a user selects one of these links, a single-sign-on operation is initiated by the identity provider. In contrast, the present invention eliminates these prerequisites, as shown by multiple exemplary embodiments of the present invention that are described hereinbelow.

Referring to FIG. 9A, the user has already authenticated to the identity provider (step 902). With step 902, the user has authenticated to the identity provider at some previous point in time and currently has a valid session with the identity provider; there are no requirements on the reasons for which a session was established at step 902. It should be noted that other scenarios for initiating a single-sign-on operation may have a different sequence of steps. For example, a user might browse information that is provided by an identity provider without an authenticated session; at some later point in time after some interaction with the user, the user requests a resource such that the identity provider determines that the identity provider only performs certain operations for authenticated users, thereafter initiating an authentication operation with the user.

The single-sign-on process commences at the identity provider by sending to the client from the identity provider an offer to provide access to federated resources (step 904); the offer may be in the form of hyperlinks to resources at federated web sites or, more generally, at federated domains, and the offer may be made in the form of an HTTP response message in response to a previous HTTP request message from the client (not shown) to view a particular web page on the identity provider's web site. The user then selects one of the offered federated resources at service providers that are known to the identity provider (step 906); the selection may be accomplished by an HTTP request message from the client to the identity provider.

If the user does yet have a federated identity that may be used for a federated single-sign-on operation, then the identity provider creates an alias for the user (step 908). The identity provider builds a message for requesting access to the selected federated resource on behalf of the user such that the message also includes a single-sign-on request (step 910), i.e. a push-type single-sign-on request. A push-type single-sign-on request originates with an identity provider and is pushed to a service provider in an unsolicited manner in order to provide the service provider with information that authenticates a user identity; in contrast, a pull-type single-sign-on request originates with a service provider that is attempting to pull authentication information for a user in a solicited manner. Alternatively, a push-type single-sign-on operation can be emulated, particularly when a push-type single-sign-on operation is not supported explicitly. An emulated push-type single-sign-on operation occurs when an identity provider issues a request to a service provider, e.g., via a specialized service at the service provider such as an intersite transfer service, whereupon the service provider issues a single-sign-on request to the identity provider; after the identity provider responds to the request from the service provider, the processing steps are the same as if an explicit push-type single-sign-on operation has occurred.

The identity provider sends the resource request with the single-sign-on request to the client (step 912), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). The redirect message redirects the client to the appropriate location, e.g., as identified by a URI within the "Location" header of the redirect message, that identifies the appropriate service at the service provider that controls access to the requested federated resource. In response to receiving the redirect message from the identity provider, the client sends an HTTP Get message to the appro-

32

priate service at the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 914).

The service provider receives and processes the received request message from the client (step 916). At step 916, the service provider retrieves from the received message an alias identifier or alias information that has been associated with the user by the identity provider but which is not recognized by the service provider as being associated with a previously existing user account at the service provider. Hence, at step 916, the service provider determines that the user does not have a user account that links the user with the identity provider, i.e. a linked user account that informs the service provider that the service provider should accept information for a single-sign-on operation from the identity provider in order to authenticate the user. In other words, at step 916, the service provider determines that the service provider does not have a user account that links a user account at the service provider with a user account at the identity provider.

This recognition is significant for the following reasons. It should be noted that the user may already have one or more accounts at the service provider. These accounts may be used independently because a unique user account is based on a unique user identifier; given a user identifier, the service provider determines the privileges that are associated with the user identifier, i.e. a particular user account. Given that a linked user account is independent of any other user account that the user may have at the service provider, and given that a linked user account requires a unique user identifier to be associated with the linked user account, a linked user account is based on a user identifier that is independent and unique in comparison with any other user identifier that is known to the service provider; this particular user identifier is known as an alias identifier, although some form of alias information within multiple data variables may be used in place of a single alias data variable in some embodiments.

Therefore, after the service provider recognizes that a provided alias identifier is not associated with a previously existing user account at the service provider, the service provider begins to perform operations in order to ensure that the single-sign-on operation is performed successfully. Since the user had not yet been federated with the service provider, the service provider creates a new account for the user with the alias information that has been provided by the identity provider within the request message (step 918) such that the user has an active session at the service provider.

It should be noted that the minimum information required to create this account will be any local information that is required to identify the account (which is generated internally by the service provider) and any alias information that is provided by the identity provider; thereafter, the newly created user account is linked to the identity provider based on the provided alias for the user such that the service provider is able to perform a single-sign-on operation on behalf of the user in cooperation with the identity provider. If the request to the service provider includes user attributes as well as an alias identifier for the user, then these attributes may be added to the local account; however, it should be noted that, in some embodiments, the service provider may create a linked user account using only the alias identifier without any additional user attribute information from the identity provider, possibly by assigning a local set of default user attributes that are determined by the service provider and that are independent of any information that is received from the identity provider. Whether any additional attributes are provided or not, what should be noted is that this account would preferably not be enabled for direct authentication; hence, the only manner for

US 7,631,346 B2

33

the user to gain access to resources at the service provider would be as the result of a session established from a single-sign-on operation triggered by the identity provider.

After the linked user account has been created, the service provider then performs the requested resource access (step 920). After performing the resource access, the service provider responds by sending an HTTP response message to the client (step 922), thereby concluding the process.

The single-sign-on operation of the present invention, e.g., the embodiment that is shown in FIG. 9A, differs from the single-sign-on solutions of the prior art, e.g., the operation that is shown in FIG. 8, because the service provider recognizes during the single-sign-on operation of the present invention that the service provider does not have a user account for the user that links the user to an account at an identity provider in order to support single-sign-on operations, yet with the present invention the service provider is able to dynamically perform operations to allow the single-sign-on operation to proceed. More specifically, the service provider does not have, e.g., within its user registries or databases, enough information that allows the service provider to determine the user's local identity, and therefore the user's privileges, for the single-sign-on operation; without this information, the service provider cannot determine the appropriate set of privileges to be given to the user and, therefore, the type of session/access control rights to give the user, if the service provider were to allow the single-sign-on operation to proceed. In the prior art, the service provider cannot automatically create an active session for the user and allow access to protected resources; with the present invention, the service provider dynamically performs a runtime linked-user-account creation operation at the service provider by creating a linked user account based on the user identity, and possibly attribute information, that has been provided by the identity provider to the service provider, e.g., as provided in a request that has been redirected from the identity provider through the client. The service provider is willing and able to perform such operations based on its trust relationship with the identity provider with their federated computing environment. In this manner, the single-sign-on request can be fulfilled by the service provider, which results in the creation of an active session for the user, and the request for access to the protected resource can proceed.

In a manner similar to that shown in FIG. 9A, FIG. 9B depicts a process by which an identity provider may request a single-sign-on operation at a selected service provider; similar elements in the figures are identified by similar reference numerals. However, whereas FIG. 9A depicts only a generalized runtime user account creation operation at step 918, the process that is shown in FIG. 9B differs from the process that is shown in FIG. 9A with respect to the runtime linked-user-account creation operation, which stretches over steps 930-942 in FIG. 9B. Unlike the process that is shown in FIG. 9A, in the process that is shown in FIG. 9B, the service provider is not able to immediately create, or to complete immediately the creation of, a user account at the service provider based on the information that has been provided by the identity provider to the service provider.

Referring now to FIG. 9B, the single-sign-on processing in FIG. 9B (step 930) differs because the service provider recognizes during the single-sign-on operation that the service provider does not have a pre-existing user account for the identity that is claimed or asserted in the single-sign-on request from the identity provider, i.e. a pre-existing user account that links the service provider to the identity provider on behalf of the user, and further that the information contained in the single-sign-on request is not sufficient to create

34

a valid account at the service provider. Thus, the service provider recognizes that it requires additional information about the user from the identity provider. More specifically, the service provider does not have sufficient user attribute information to create an active account for the user; for example, there may be attributes that are required by the service provider but were not included in the received single-sign-on request. Because of these additional requirements, the service provider is not yet able to create, or to completely create, whatever user account registry/database entries that it requires based on the information it has received.

In the embodiment that is shown in FIG. 9B, the service provider responds by sending an HTTP redirect message (HTTP Response message with status/reason code "302") to the client (step 932); the message from the service provider contains a request for additional user attribute information. The redirect message redirects the client to the identity provider using a return URI that was previously provided by the identity provider to the service provider. In response to receiving the redirect message from the service provider, the client sends an HTTP Get message to the identity provider as indicated by the URI in the HTTP redirect message from the service provider (step 934).

The identity provider then processes the received message (step 936) to build a response that contains user attribute information that is stored by the identity provider about the user of the client. The manner in which specific user attributes are identified may vary. For example, the user attribute information that is provided by the identity provider may include user attribute information that was explicitly requested by the service provider. Additionally or alternatively, the user attribute information that is provided by the identity provider may include user attribute information that was implicitly requested by the service provider, i.e. user attribute information that has been determined by the identity provider to be sufficient for performing a user account creation operation at the service provider. In addition, the identity provider may perform an operation to reconcile the received request for additional user attribute information with the identity provider's previous single-sign-on request to ensure that a service provider is not attempting to obtain user attributes without sufficient reason to do so.

After the identity provider builds the message at step 936, the identity provider sends the message with the additional user attributes to the client (step 938), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). The redirect message redirects the client to the appropriate location, e.g., as identified by a URI within the "Location" header of the redirect message, that identifies the appropriate service at the service provider; the appropriate location may have been provided by the service provider in its request for the additional user attributes. In response to receiving the redirect message from the identity provider, the client sends an HTTP Get message to the appropriate service at the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 940).

Given the additional user attribute information in the received message, the service provider performs a runtime linked-user-account creation operation at the service provider (step 942) by creating a linked user account based on the received user attribute information; in this manner, the single-sign-on request (and any subsequent single-sign-on requests) can be fulfilled by the service provider, which also creates an active session for the user, and the request for access to the protected resource can proceed at steps 920 and 924. In some embodiments, the service provider may preliminarily create

US 7,631,346 B2

35

the user account yet postpone the completion of the creation of the user account; in these embodiments, the service provider completes the creation of the user account at step 942. It should be noted that the processes are described in the context of an HTTP redirection-based attribute retrieval, but these processes could be implemented with a back-channel approach, such as a SOAP/HTTP-based SAML attribute query from the service provider to the identity provider.

With reference now to FIGS. 9C-9E, dataflow diagrams depict an HTTP-redirection-based single-sign-on operation that is initiated by a federated identity provider to obtain access to a protected resource at a federated service provider with alternative methods for obtaining user attributes by the federated service provider in accordance with an embodiment of the present invention. The processes that are shown in FIGS. 9C-9E differ from the processes that are shown in FIGS. 9A-9B primarily in the manner in which the service provider obtains user attributes during a single-sign-on operation; the processes that are shown in FIGS. 9A-9B and in FIGS. 9C-9E are both initiated by an identity provider. In addition, in the dataflow that is shown in FIG. 9B, a service provider performs the runtime linked-user-account creation operation at step 942; in contrast, in the dataflow that is shown in FIGS. 9C-9E, the service provider may perform the runtime linked-user-account creation operation over multiple steps by partially creating a linked user account and then later completing the runtime linked-user-account creation operation, as described in more detail hereinbelow.

Referring now to FIG. 9C, the process commences with a user browsing public resources that are hosted by an identity provider (step 952), i.e. resources that are not protected resources that require an authentication operation with respect to the user prior to accessing the resources. At some subsequent point in time, the user's client sends to the identity provider a request for access to a protected resource that requires an authentication operation (step 954); for example, the user might attempt to browse information that the identity provider maintains about resources at service providers within a federated computing environment in which the identity provider participates with service providers, i.e. the identity provider's federated partners. In response to the user request, the identity provider performs an authentication operation with the user (step 956). In this example, the identity provider thereafter offers links to resources at federated service providers (step 958), and the user then selects or initiates an operation to access a resource at a service provider (step 960).

If the user does yet have an alias identifier that may be used for a federated single-sign-on operation, then the identity provider creates an alias for the user (step 962), which may include performing other operations to associate the alias identifier with the user, particular to associate the alias identifier with other information that is associated with the user, e.g., user attribute information. The identity provider builds a message for requesting access to the selected federated resource on behalf of the user such that the message also includes a single-sign-on request (step 964), i.e. a push-type single-sign-on request. The identity provider sends the resource request with the single-sign-on request to the client (step 966), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). The redirect message redirects the client to the appropriate location, e.g., as identified by a URI within the "Location" header of the redirect message, that identifies the appropriate service at the service provider that controls access to the requested federated resource. In response to receiving the redirect message from the identity provider, the client sends

36

an HTTP Get message to the appropriate service at the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 968).

The service provider then processes the single-sign-on response (step 970), which may include, e.g., extracting the newly created alias identifier for the user and extracting any user attribute information about the user that has been preliminarily provided by the identity provider to the service provider. The service provider attempts to create a new user account (step 972) but either is not able to immediately create or is not able to create a fully appropriate user account at the service provider based on the federated user identity information that has been provided by the identity provider to the service provider in the single-sign-on response. In other words, depending on the implementation, the service provider either fails to create or determines that it cannot create a user account at this point in time, or the service provider creates a user account with limited-time or limited-access privileges. More specifically, the service provider does not have, e.g., within the combination of its user registries or databases and the information that is initially provided by the identity provider, the information required to allow the service provider to determine the user's appropriate set of privileges; without this information, the service provider cannot determine the type of session/access control rights to give the user. Hence, the service provider recognizes during the single-sign-on operation that the service provider does not yet have a linked user account for the user while also recognizing that the service provider requires additional information about the user from the identity provider (step 974).

The manner in which the service provider pulls additional user attribute information from the identity provider to complete the user account creation operation may vary; two examples of variations are shown in FIG. 9D and in FIG. 9E. FIG. 9D illustrates a front-channel attribute retrieval operation, whereas FIG. 9E illustrates a back-channel attribute retrieval operation. Hence, the data flow diagram that is shown in FIG. 9C continues into either FIG. 9D or FIG. 9E; in both cases, the dataflow diagrams in FIG. 9D and FIG. 9E conclude with similar steps that are denoted with similar reference numerals.

Referring now to FIG. 9D, the service provider responds to its determination of its lack of user attribute information by sending an HTTP redirect message (HTTP Response message with status/reason code "302") to the client (step 976); the message from the service provider contains a request for additional user attribute information. The redirect message redirects the client to the identity provider using a return URI that was previously provided by the identity provider to the service provider. In response to receiving the redirect message from the service provider, the client sends an HTTP Get message to the identity provider as indicated by the URI in the HTTP redirect message from the service provider (step 978). The identity provider then processes the received message (step 980) to build a response that contains user attribute information that is stored by the identity provider about the user of the client. The manner in which specific user attributes are identified may vary. For example, the user attribute information that is provided by the identity provider may include user attribute information that was explicitly requested by the service provider. Additionally or alternatively, the user attribute information that is provided by the identity provider may include user attribute information that was implicitly requested by the service provider, i.e. user attribute information that has been determined by the identity provider to be sufficient for performing a user account creation operation at the service provider. In addition, the identity provider may

US 7,631,346 B2

37

perform an operation to reconcile the received request for additional user attribute information with the service provider's previous single-sign-on request to ensure that a service provider is not attempting to obtain user attributes without sufficient reason to do so.

After the identity provider builds the message at step 980, the identity provider sends the message with the user attributes to the client (step 982), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). In response to receiving the redirect message from the identity provider, the client sends an HTTP Get message to the appropriate service at the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 984).

Given the user attribute information in the received message, the service provider performs or completes a user account creation operation at the service provider (step 986) based on the received user attribute information; in this manner, the single-sign-on request can be fulfilled by the service provider, which also creates an active session for the user, and the request for access to the protected resource can proceed. In both FIG. 9D and FIG. 9E, the service provider provides access to the originally requested protected resource (step 988), and the service provider sends an HTTP Response message to the client that contains information that is derived from accessing the protected resource (step 990), thereby concluding the process.

Referring now to FIG. 9E, the service provider responds to its determination of its lack of user attribute information by sending a SOAP message directly from the service provider to the identity provider (step 992); the message from the service provider contains a request for required user attribute information. The identity provider then processes the received message (step 994) to build a response that contains user attribute information that is stored by the identity provider about the user of the client; again, the manner in which specific user attributes are identified may vary as described above. The identity provider sends a SOAP response message with the required user attributes to the client (step 996). Given the user attribute information in the received message, the service provider performs or completes a runtime user account creation operation at the service provider (step 998) based on the received user attribute information; in this manner, the single-sign-on request can be fulfilled by the service provider, which also creates an active session for the user, and the request for access to the protected resource can proceed at steps 988 and 990.

With reference now to FIG. 10, a flowchart depicts a more detailed process for performing a runtime linked-user-account creation operation at a service provider during a single-sign-on operation that has been initiated by an identity provider. The flowchart that is shown in FIG. 10 depicts a service-provider-centered perspective for some of the processing that occurs at a service provider within the dataflow diagram that is shown in FIG. 9B.

The process commences when the service provider receives a request from an identity provider to access a protected resource at the service provider on behalf of a user of a client based on a single-sign-on operation (step 1002). It should be noted that the protected resource may be an endpoint that corresponds to the service provider's functionality for fulfilling a single-sign-on request; in other words, it is possible that the request from the identity provider is redirected directly to the known functionality to accomplish the single-sign-on operation because the user has not requested a particular back-end resource but simply overall access to the service provider. The service provider extracts a user identifier

38

from the received request message (step 1004) and makes a determination as to whether or not the user identifier is recognized (step 1006).

If the user identifier is not recognized by the service provider, then the service provider cannot create an active session with the appropriate security considerations for protected access to its hosted computational resources. The service provider extracts any user attribute information that might be embedded in the received message (step 1008), and a determination is made as to whether or not the service provider has sufficient information about the user to create a user account for the user at that time (step 1010), e.g., as would be required to generate an entry into a user registry or whatever operations are typically performed by the service provider to create a local user account for the user at the service provider.

If the service provider does not have sufficient information about the user to create a user account for the user, the service provider may send a request to the identity provider to obtain additional user attribute information (step 1012); this may be performed in a synchronous or asynchronous manner. The service provider subsequently receives additional user attributes from the identity provider (step 1014).

It should be noted that an embodiment of the present invention may be implemented such that a user attribute retrieval operation by a service provider may be performed with respect to an attribute information provider. For example, a service provider may send a request for user attributes to an attribute information provider rather than an identity provider. Alternatively, a service provider may send a request for user attributes to an identity provider, which subsequently enlists assistance by sending a request to an attribute information provider, thereby acting as an intermediate trusted agent on behalf of the service provider. Additional information about the usage of an attribute information provider within the context of a federated computing environment may be found in Blakley et al., "Method and system for user-determined attribute storage in a federated environment", U.S. Patent Application Publication US 2004/0128378 A1, published Jul. 1, 2004, based on U.S. patent application Ser. No. 10/334,605, filed Dec. 31, 2002, which has a common assignee with the present patent application and is hereby incorporated by reference.

After receiving the additional user attributes at step 1014, or based on any user attribute information that may have been within the original request as extracted at step 1008, the service provider performs a linked user account creation operation (step 1016); as noted above, the operations that are performed to create a linked user account for the user at the service provider may vary. After the linked user account has been created at the service provider, the service provider may be able to proceed with the processing of the original request.

The service provider then determines whether there is sufficient information for activating the newly created account for the user (step 1018). If the service provider does not yet have sufficient information for activating the user's account, then a determination is made as to whether the service provider has already made too many attempts to obtain user attributes for activating the user account (step 1020); if not, then the process branches back to step 1012 to make an attempt to obtain the necessary user attributes. Otherwise, the service provider performs some type of error handling (step 1022), which may entail sending an error response back to the identity provider.

If the service provider has sufficient information for activating the user's account at step 1018, then the service provider creates an active session for the user (step 1024), either based on a successful authentication of a recognized user

US 7,631,346 B2

39

identity at step 1006 or based on the newly created user identity at step 1016. The service provider then generates a response for the original request to access the protected resource (step 1026), and the response is sent by the service provider to the identity provider (step 1028), thereby concluding the process.

The exemplary dataflow that is described with respect to FIG. 9B or the exemplary process that is described with respect to FIG. 10 can be described in the context of the exemplary data processing systems that are shown in FIG. 7 or in FIG. 3.

In order to perform a single-sign-on operation, the identity and attribute service (I&AS) 356 or 718 needs to be able to recognize a user identity from a single-sign-on request within a user registry in some manner. The user registry can be a local registry, e.g., private to the installation of the federated functionality, such as federation user registry 358 or 720, or it could be an enterprise registry that is shared by other applications within an enterprise, such as enterprise user registry 338 or 722. The user account information or user registry information needs to allow I&AS 356 or 718 to build the appropriate information that identifies the user locally. This information may be represented by a username, a set of attributes, e.g., groups and/or roles and/or entitlements, or an opaque identifier, e.g., a NameIdentifier as described within the Liberty Alliance specifications. If the information asserted by the identity provider about the user for which a single-sign-on is being requested cannot be found within a local registry, then I&AS 356 or 718 is not able to build information about the user in a local manner, e.g., to create valid credentials that are used by entities within the local enterprise; in addition, the point-of-contact server 342 or 702 is not able establish a session for the user, and the user is not able to access protected resources.

The present invention provides a mechanism to prevent the generation of some form of error code for an unrecognized user as would be performed in prior art approaches. In the embodiment of the present invention that is shown in the figures, I&AS 356 or 718 may attempt to create a user account, record, or entry, as appropriate for the data storage requirements of the enterprise when the received user identity information is unrecognized. I&AS 356 or 718 performs these operations based on the trust relationship between the federated partners of the identity provider and the service provider, e.g., as provided for within a configured policy that allows for this type of action. The user identity information that is received in the original request may be an actual username value or an opaque data value such as a Liberty Alliance NameIdentifier; this user identity information may be used as a pointer into a user registry from which this user's information would be accessed at some subsequent point in time, or it may be used in a temporary manner until permanent data records are created, e.g., as a pointer into a cache that contains temporary information.

If the original single-sign-on request contains attribute data about a user, then the attribute information may be added directly to a user registry when creating a user account for the user locally. However, the originally received request does not necessarily contain all of the information that is required locally to create a user account for the user. In this case, I&AS 356 or 718 working with single-sign-on protocol service (SPS) 354 or 716 may issue an attribute query, such as a SAML attribute query and/or a WS-AttributeService request, to the user's identity provider to retrieve additional information about the user. As a result, the service provider is able to create a user account for the user in a runtime manner, i.e.,

40

while the single-sign-on operation is suspended or, from another temporal viewpoint, concurrently with or as part of the single-sign-on operation.

The level of trust that is accorded to this type of runtime linked-user-account creation operation by the service provider may vary; it is not necessarily the case that all service providers would be willing to allow a completely automated, dynamically determined, linked-user-account creation operation. Hence, in some cases, a service provider may require that a local workflow operation must be undertaken, e.g., a type of local administrative approval process. Rather than directly creating a user account for a user in a completely automated process, the federated user lifecycle management (FULM) application/service 352 or 708 might store the user information, including additional, out-of-band-retrieved user attributes, into some form of local datastore, which may, in turn, trigger a local workflow/approval process. This requirement allows an administrative user at the service provider to approve the creation of the user account in accordance with local policy requirements, etc. As a result, the runtime user account creation operation may be asynchronous, in which case the service provider may send a message to the user to indicate that an account is being created for the user at the service provider and to indicate that the user can attempt to perform a login operation at the service provider at some subsequent point in time. If the user needs to be added to more than an I&AS-accessible user registry, then FULM service 352 or 708 may send this information to a local datastore, from which a local user account creation process is initiated; in this case, accounts/records can be created for the user in multiple destinations in addition to a local I&AS-accessible datastore. It should be noted that the service provider may choose to grant the user a limited-time, limited-access session, thereby restricting the user to a subset of accessible resources rather than a complete set of resources until some later event, e.g., completion of some type of workflow process for approving broader access, or until some later determination is made as to the privileges that should be given to the user; thereafter, the user account would be created with an appropriate level of access to resources.

With reference now to FIG. 11A, a dataflow diagram depicts an HTTP-redirection-based pull-type single-sign-on operation that is initiated by a federated service provider to allow access to a protected resource at the federated service provider while performing a runtime linked-user-account creation operation at the federated service provider in accordance with an embodiment of the present invention. The processes that are shown in FIGS. 11A-11D differ from the processes that are shown in FIGS. 9A-9B primarily in the perspective of the origination of the single-sign-on operation; the processes that are shown in FIGS. 9A-9B are initiated by an identity provider, whereas the processes that are shown in FIGS. 11A-11D are initiated by a service provider.

Referring now to FIG. 11A, the process commences with a user browsing public resources that are hosted by a service provider (step 1102), i.e. resources that are not protected resources that require an authentication operation with respect to the user prior to accessing the resources. At some subsequent point in time, the user's client sends to the service provider a request for access to a protected resource that requires an authentication operation (step 1104). The service provider recognizes that it does not have an identifier for the user's preferred identity provider, and the service provider prompts the user to provide the information in some manner (step 1106), e.g., through user-selectable controls in a web page. The client then sends to the service provider the appro-

US 7,631,346 B2

41

priate information about the preferred identity provider as selected by the user (step 1108).

The service provider then builds a pull-type single-sign-on request for the user (step 1110). In this example, the service provider assumes that the user is a federated user, e.g., by assuming that the identity provider maintains some type of federated alias identifier for the user. The service provider sends the single-sign-on request to the client (step 1112), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). In response to receiving the redirect message from the service provider, the client sends an HTTP Get message to the identity provider as indicated by the URI in the HTTP redirect message from the service provider (step 1114).

In response to receiving the pull-type single-sign-on request, the identity provider performs an authentication operation with the client with respect to the user of the client, if required (step 1116); for example, the authentication operation may not be required if the user is already logged on at the identity provider, i.e. if the user already has an active session at the identity provider. The identity provider evaluates the received request (step 1118), and the identity provider determines that the service provider has not provided a user identity to the identity provider as part of the federation request. If the identity provider further determines that the user does not yet have a federated identity, then the identity provider creates a federated identity for the user, e.g., an alias identifier for the user (step 1120). The identity provider builds a pull-type single-sign-on response (step 1122) that contains the newly created, federated identity for the user and optionally contains additional user attribute information that is managed by the identity provider about the user; this pull-type single-sign-on response may or may not have the same data format characteristics as a push-type single-sign-on response. The identity provider sends the single-sign-on response to the client (step 1124), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). In response to receiving the redirect message from the identity provider, the client sends an HTTP Get message to the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 1126).

The service provider then processes the single-sign-on response (step 1128), which may include, e.g., extracting the newly created federated identifier for the user and may also include the extraction of additional user attribute information about the user. The service provider then creates a new linked user account for the user with the federated identifier that was provided by the identity provider (step 1130), which may possibly also entail using some user attribute information about the user from the identity provider if the identity provider has sent such information and if the service provider needs this information while creating the new user account. After the user has an active session based on the newly created user account, the service provider provides access to the originally requested protected resource (step 1132), and the service provider sends an HTTP Response message to the client that contains information that is derived from accessing the protected resource (step 1134), thereby concluding the process.

With reference now to FIGS. 11B-11D, a set of dataflow diagrams depict an HTTP-redirect-based pull-type single-sign-on operation that is initiated by a federated service provider to allow access to a protected resource at the federated service provider with additional retrieval of user attribute information from a federated identity provider while performing a runtime linked-user-account creation operation at the federated service provider in accordance with an embodi-

42

ment of the present invention. In a manner similar to that shown in FIG. 11A, FIG. 11B depicts a process by which a service provider may request a single-sign-on operation at a selected identity provider; similar elements in the figures are identified by similar reference numerals. However, whereas FIG. 11A depicts only a generalized runtime linked-user-account creation operation at step 1130, the process that is shown in FIG. 11B differs from the process that is shown in FIG. 11A with respect to the runtime linked-user-account creation operation, which stretches over steps 1150-1164 in FIGS. 11A-11B.

Referring now to FIG. 11B, unlike the process that is shown in FIG. 11A, the service provider attempts to create a new user account (step 1150) but either is not able to immediately create or is not able to create a fully appropriate user account at the service provider based on the federated user identity information that has been provided by the identity provider to the service provider in the single-sign-on. In other words, depending on the implementation, the service provider either fails to create or determines that it cannot create a user account at this point in time, or the service provider creates a user account with limited-time or limited-access privileges. Hence, the single-sign-on processing in FIG. 11B differs because the service provider recognizes during the single-sign-on operation that the service provider does not yet have a linked user account for the user while also recognizing that the service provider requires additional information about the user from the identity provider (step 1152). More specifically, the service provider does not have, e.g., within its user registries or databases, enough information that allows the service provider to determine the user's appropriate set of privileges; without this information, the service provider cannot determine the type of session/access control rights to give the user.

The manner in which the service provider pulls additional user attribute information from the identity provider to complete the linked-user-account creation operation may vary; two examples of variations are shown over steps 1154-1164 in FIG. 11C or over steps 1172-1178 in FIG. 11D. FIG. 11C illustrates a front-channel attribute retrieval operation, whereas FIG. 11D illustrates a back-channel attribute retrieval operation. Hence, the data flow diagram that is shown in FIG. 11B continues into either FIG. 11C or FIG. 11D; in both cases, the dataflow diagrams in FIG. 11C and FIG. 11D conclude with similar steps. In both FIG. 11C and FIG. 11D, the service provider provides access to the originally requested protected resource at step 1132, and the service provider sends an HTTP Response message to the client that contains information that is derived from accessing the protected resource at step 1134, thereby concluding the process.

Referring now to FIG. 1C, the service provider responds to its determination of its lack of user attribute information by sending an HTTP redirect message (HTTP Response message with status/reason code "302") to the client (step 1154); the message from the service provider contains a request for additional user attribute information. The redirect message redirects the client to the identity provider using a return URI that was previously provided by the identity provider to the service provider. In response to receiving the redirect message from the service provider, the client sends an HTTP Get message to the identity provider as indicated by the URI in the HTTP redirect message from the service provider (step 1156). The identity provider then processes the received message (step 1158) to build a response that contains user attribute information that is stored by the identity provider about the user of the client. The manner in which specific user

US 7,631,346 B2

43

attributes are identified may vary. For example, the user attribute information that is provided by the identity provider may include user attribute information that was explicitly requested by the service provider. Additionally or alternatively, the user attribute information that is provided by the identity provider may include user attribute information that was implicitly requested by the service provider, i.e. user attribute information that has been determined by the identity provider to be sufficient for performing a linked-user-account creation operation at the service provider. In addition, the identity provider may perform an operation to reconcile the received request for additional user attribute information with the service provider's previous single-sign-on request to ensure that a service provider is not attempting to obtain user attributes without sufficient reason to do so.

After the identity provider builds the message at step 1158, the identity provider sends the message with the additional user attributes to the client (step 1160), e.g., in the form of an HTTP redirect message (HTTP Response message with status/reason code "302"). In response to receiving the redirect message from the identity provider, the client sends an HTTP Get message to the appropriate service at the service provider as indicated by the URI in the HTTP redirect message from the identity provider (step 1162).

Given the additional user attribute information in the received message, the service provider performs or completes a runtime linked-user-account creation operation at the service provider (step 1164) based on the received user attribute information; in this manner, the single-sign-on request can be fulfilled by the service provider, which also creates an active session for the user, and the request for access to the protected resource can proceed at steps 1132 and 1134.

Referring now to FIG. 11D, the service provider responds to its determination of its lack of user attribute information by sending a SOAP message directly from the service provider to the identity provider (step 1172); the message from the service provider contains a request for additional user attribute information. The identity provider then processes the received message (step 1174) to build a response that contains user attribute information that is stored by the identity provider about the user of the client; again, the manner in which specific user attributes are identified may vary as described above. The identity provider sends a SOAP response message with the additional user attributes to the client (step 1176). Given the additional user attribute information in the received message, the service provider performs or completes a runtime linked-user-account creation operation at the service provider (step 1178) based on the received user attribute information; in this manner, the single-sign-on request can be fulfilled by the service provider, which also creates an active session for the user, and the request for access to the protected resource can proceed at steps 1132 and 1134.

#### CONCLUSION

The advantages of the present invention should be apparent in view of the detailed description of the invention that is provided above. When an identity provider attempts to initiate a single-sign-on operation on behalf of a user at a service provider in order to obtain access to a controlled resource that is hosted by the service provider, it is possible that the service provider would not recognize the user identifier or other user identity information in the received request. In the prior art, this scenario would generate an error.

With the present invention, the service provider may dynamically perform a linked-user-account creation opera-

44

tion as part of the single-sign-on operation. If necessary, the service provider can pull additional user attribute information from the identity provider in order to obtain the required user attributes for the user in a manner that is locally required by the identity management functionality of the service provider.

"It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes associated with the present invention are capable of being distributed in the form of instructions in a computer readable medium. Examples of computer readable media include media such as EPROM, ROM, tape, paper, floppy disc, hard disk drive, RAM, and CD-ROMs."

A method is generally conceived to be a self-consistent sequence of steps leading to a desired result. These steps require physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It is convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, parameters, items, elements, objects, symbols, characters, terms, numbers, or the like. It should be noted, however, that all of these terms and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities.

The description of the present invention has been presented for purposes of illustration but is not intended to be exhaustive or limited to the disclosed embodiments. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiments were chosen to explain the principles of the invention and its practical applications and to enable others of ordinary skill in the art to understand the invention in order to implement various embodiments with various modifications as might be suited to other contemplated uses.

What is claimed is:

1. A method for managing user authentication within a distributed data processing system, wherein a first system and a second system interact within a federated computing environment and support single-sign-on operations in order to provide access to protected resources, at least one of the first system and the second system comprising a processor, the method comprising:

triggering a single-sign-on operation on behalf of the user in order to obtain access to a protected resource that is hosted by the second system, wherein the second system requires a user account for the user to complete the single-sign-on operation prior to providing access to the protected resource;

receiving from the first system at the second system an identifier associated with the user; and

creating a user account for the user at the second system based at least in part on the received identifier associated with the user after triggering the single-sign-on operation but before generating at the second system a response for accessing the protected resource, wherein the created user account supports single-sign-on operations between the first system and the second system on behalf of the user.

2. The method of claim 1 further comprising:

creating an alias identifier for the user at the first system after triggering the single-sign-on operation.

3. The method of claim 1 further comprising:

sending a message from the second system to the first system to pull authentication information for the user

## US 7,631,346 B2

45

from the first system to the second system in order to trigger the single-sign-on operation for the user at the second system.

4. The method of claim 1 further comprising:

receiving a message from the first system at the second system to push authentication information for the user from the first system to the second system in order to trigger the single-sign-on operation for the user at the second system.

5. The method of claim 1 further comprising:

in response to a determination at the second system that the second system does not have sufficient user attribute information to complete creation of a user account for the user at the second system, sending a request message from the second system to the first system to retrieve user attribute information; and

receiving at the second system from the first system a response message that contains user attribute information that is employed by the second system to complete creation of a user account for the user at the second system.

6. The method of claim 5 further comprising:

employing a front-channel information retrieval mechanism to obtain user attribute information.

7. The method of claim 6 further comprising:

using HyperText Transport Protocol (HTTP) in the front-channel information retrieval mechanism.

8. The method of claim 5 further comprising:

employing a back-channel information retrieval mechanism to obtain user attribute information.

9. The method of claim 8 further comprising:

using Simple Object Access Protocol (SOAP) in the back-channel information retrieval mechanism.

10. The method of claim 5 further comprising:

performing a preliminary user account creation operation to commence creation of the user account for the user prior to retrieving user attribute information for the user; and

performing a concluding user account creation operation to complete creation of the user account for the user after retrieving user attribute information for the user.

11. The method of claim 5 further comprising:

retrieving user attribute information from a fourth system by the first system.

12. The method of claim 1 wherein the first system supports an identity provider and the second system supports a service provider.

13. The method of claim 12 further comprising:

prompting the user by the service provider to provide or to select an identifier for the identity provider prior to receiving an identifier associated with the user.

14. The method of claim 1 further comprising:

in response to a determination at the second system that the second system does not have sufficient user attribute information to complete creation of a user account for the user at the second system, sending a request message to a fourth system to retrieve user attribute information; and

receiving at the second system from the fourth system a response message that contains user attribute information that is employed by the second system to complete creation of a user account for the user at the second system.

15. A computer program product on a computer-readable medium for managing user authentication within a data processing system, wherein a first system and a second system interact within a federated computing environment and sup-

46

port single-sign-on operations in order to provide access to protected resources, at least one of the first system and the second system comprising a processor, the computer program product holding computer program instructions which when executed by the data processing system perform a method comprising:

triggering a single-sign-on operation on behalf of the user in order to obtain access to a protected resource that is hosted by the second system, wherein the second system requires a user account for the user to complete the single-sign-on operation prior to providing access to the protected resource;

receiving from the first system at the second system an identifier associated with the user; and

creating a user account for the user at the second system based at least in part on the received identifier associated with the user after triggering the single-sign-on operation but before generating at the second system a response for accessing the protected resource, wherein the created user account supports single-sign-on operations between the first system and the second system on behalf of the user.

16. The computer program product of claim 15 wherein the method further comprises:

creating an alias identifier for the user at the first system after triggering the single-sign-on operation.

17. The computer program product of claim 15 wherein the method further comprises:

sending a request message from the second system to the first system to retrieve user attribute information in response to a determination at the second system that the second system does not have sufficient user attribute information to complete creation of a user account for the user at the second system; and

receiving at the second system from the first system a response message that contains user attribute information that is employed by the second system to complete creation of a user account for the user at the second system.

18. An apparatus for managing user authentication within a data processing system, wherein a first system and a second system interact within a federated computing environment and support single-sign-on operations in order to provide access to protected resources, at least one of the first system and the second system comprising a processor, the apparatus comprising:

a processor;

a computer memory holding computer program instructions which when executed by the processor perform a method comprising:

triggering a single-sign-on operation on behalf of the user in order to obtain access to a protected resource that is hosted by the second system, wherein the second system requires a user account for the user to complete the single-sign-on operation prior to providing access to the protected resource;

receiving from the first system at the second system an identifier associated with the user; and

creating a user account for the user at the second system based at least in part on the received identifier associated with the user after triggering the single-sign-on operation but before generating at the second system a response for accessing the protected resource, wherein the created user account supports single-sign-on operations between the first system and the second system on behalf of the user.

US 7,631,346 B2

47

19. The apparatus of claim 18 wherein the method further comprises:

creating an alias identifier for the user at the first system after triggering the single-sign-on operation.

20. The apparatus of claim 18 wherein the method further comprises: 5

sending a request message from the second system to the first system to retrieve user attribute information in response to a determination at the second system that the

48

second system does not have sufficient user attribute information to complete creation of a user account for the user at the second system; and  
receiving at the second system from the first system a response message that contains user attribute information that is employed by the second system to complete creation of a user account for the user at the second system.

# U.S. Patent 7,631,346 (Hinton) – Claim 1

1. A method for managing user authentication within a distributed data processing system, wherein a first system and a second system interact within a federated computing environment and support single-sign-on operations in order to provide access to protected resources, at least one of the first system and the second system comprising a processor, the method comprising:
  - triggering a single-sign-on operation on behalf of the user in order to obtain access to a protected resource that is hosted by the second system, wherein the second system requires a user account for the user to complete the single-sign-on operation prior to providing access to the protected resource;
  - receiving from the first system at the second system an identifier associated with the user; and
  - creating a user account for the user at the second system based at least in part on the received identifier associated with the user after triggering the single-sign-on operation but before generating at the second system a response for accessing the protected resource, wherein the created user account supports single-sign-on operations between the first system and the second system on behalf of the user.

Access Token Type	Description
User Access Token	The user token is the most commonly used type of token. This kind of access token is needed any time the app calls an API to read, modify or write a specific person's Facebook data on their behalf. User access tokens are generally obtained via a login dialog and require a person to permit your app to obtain one.

(57) **ABSTRACT**

A method and system for mapping the conditions of locations is provided. The method includes retrieving image data associated with a plurality of locations within a specified geographical area. The image data is compared to a plurality of stored image data that includes baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area. Condition score values associated with the plurality of locations are calculated. The condition score values indicate real time condition values associated with the plurality of locations. An overall condition score value associated with the specified geographical area is generated. A map indicating the overall condition score value is generated.

## GEOGRAPHICAL AREA CONDITION DETERMINATION

### FIELD

The present invention relates generally to a method for determining an overall condition of a geographical area and in particular to a method and associated system for generating a map illustrating the overall condition of the geographical area.

### BACKGROUND

Determining location conditions typically includes an inaccurate process with little flexibility. Presenting the location conditions may include a complicated process that may be time consuming and require a large amount of resources. Accordingly, there exists a need in the art to overcome at least some of the deficiencies and limitations described herein above.

### SUMMARY

A first aspect of the invention provides a method comprising: retrieving in real time, by a computer processor of a computing system, image data associated with a plurality of locations within a specified geographical area; comparing, by said computer processor, said image data to a plurality of stored image data, wherein said plurality of stored image data comprise baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area; calculating, by said computer processor based on results of said comparing, condition score values associated with said plurality of locations, wherein said condition score values indicate real time condition values associated with said plurality of locations; calculating, by said computer processor based on said condition score values, an overall condition score value associated with said specified geographical area; and generating, by said computer processor, a map indicating said overall condition score value associated with said specified geographical area.

A second aspect of the invention provides a computing system comprising a computer processor coupled to a computer-readable memory unit, said memory unit comprising instructions that when executed by the computer processor implements a method comprising: retrieving in real time, by said computer processor, image data associated with a plurality of locations within a specified geographical area; comparing, by said computer processor, said image data to a plurality of stored image data, wherein said plurality of stored image data comprise baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area; calculating, by said computer processor based on results of said comparing, condition score values associated with said plurality of locations, wherein said condition score values indicate real time condition values associated with said plurality of locations; calculating, by said computer processor based on said condition score values, an overall condition score value associated with said specified geographical area; and generating, by said computer processor, a map indicating said overall condition score value associated with said specified geographical area.

A third aspect of the invention provides a computer program product, comprising a computer readable hardware storage device storing a computer readable program code, said computer readable program code comprising an algorithm that when executed by a computer processor of a com-

2

puting system implements a method, said method comprising: retrieving in real time, by said computer processor, image data associated with a plurality of locations within a specified geographical area; comparing, by said computer processor, said image data to a plurality of stored image data, wherein said plurality of stored image data comprise baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area; calculating, by said computer processor based on results of said comparing, condition score values associated with said plurality of locations, wherein said condition score values indicate real time condition values associated with said plurality of locations; calculating, by said computer processor based on said condition score values, an overall condition score value associated with said specified geographical area; and generating, by said computer processor, a map indicating said overall condition score value associated with said specified geographical area.

The present invention advantageously provides a simple method and associated system capable of determining location conditions.

### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a system for enabling a process for determining an overall condition of a geographical area, in accordance with embodiments of the present invention.

FIGS. 2A-2C illustrate an implementation example executed by the system for enabling a process for determining an overall condition of a geographical area, in accordance with embodiments of the present invention.

FIGS. 3A and 3B illustrate maps illustrating conditions of differing geographical areas, in accordance with embodiments of the present invention.

FIG. 4 illustrates an algorithm detailing a process flow enabled by the system of FIG. 1 for performing a process for scoring conditions, in accordance with embodiments of the present invention.

FIG. 5 illustrates an algorithm detailing a process flow enabled by the system of FIG. 1 for scoring conditions and presenting results, in accordance with embodiments of the present invention.

FIG. 6 illustrates a computer system used by or comprised by the system of FIG. 1 for enabling a process for scoring conditions and presenting results, in accordance with embodiments of the present invention.

### DETAILED DESCRIPTION

FIG. 1 illustrates a system **100** for enabling a process for determining an overall condition of a geographical area, in accordance with embodiments of the present invention. System **100** performs a process that includes:

1. Receiving a real time video feed (e.g., a video stream, still video images, etc.) from a plurality of cameras located in a geographical area (e.g., a neighborhood).
2. Pre-specifying a geographical area condition (e.g., health) measure.
3. Processing the real time video feed by comparing the real time video feed to stored video images corresponding to a specified measure.
4. Calculating a numerical value for the specified measure based on the comparison.
5. Generating a map depicting the geographical area and the numerical value.

System **100** of FIG. 1 includes devices **5a** . . . **5n** and image data systems **29** connected through a network **7** to a comput-

## US 9,245,183 B2

3

ing system **14**. Network **7** may include any type of network including, inter alia, a local area network, (LAN), a wide area network (WAN), the Internet, a wireless network, etc. Devices **5a** . . . **5n** may include any type of computing devices or software systems including, inter alia, a computer (PC), a laptop computer, a tablet computer, a server, a PDA, a smart phone, a secure Website, an application, etc. Image data systems **29** may include any type of image data retrieval systems for retrieving image data (e.g., a video stream, still video images, etc.) from, inter alia, cameras (e.g., traffic cameras, security cameras, personal cameras, etc.), social networking Websites, etc. Computing system **14** may include any type of computing system(s) including, inter alia, a computer (PC), a laptop computer, a tablet computer, a server, etc. Computing system **14** includes a memory system **8**. Memory system **8** may include a single memory system. Alternatively, memory system **8** may include a plurality of memory systems. Memory system **8** includes software **17**.

Software **17** enables a process for identifying a condition or health of specific locations (e.g., a specified geographical area such as a neighborhood) through analysis of image data retrieved from image data systems **29**. System **100** utilizes the image data to objectively determine a condition or health of a specified geographical area vs. physically or virtually visiting the specified geographical area. Image data systems **29** generate unstructured data that is filtered and analyzed for relevant elements. The unstructured data is extrapolated to determine a condition for the specified geographical area. The unstructured data may identify, inter alia, a condition of a village green, a condition of residential landscaping, debris left in roadways, a condition of residential houses (e.g., paint damage, damaged shingles, etc.), etc. Additionally, historical health condition data (for the geographical area) are retained (e.g., in memory system **8** and/or data image systems **29**) to determine whether the geographical area has improved its condition or has deteriorated. System **100** generates personalized assessments of geographical area conditions associated with potential activities including, inter alia, travel, home purchasing, etc. Additionally, system **100** generates (based on analysis of the unstructured data) a score based on user-defined parameters for each location (in the specified geographical area). The generated scores are plotted on a scalable map, table, or chart for reference.

System **100** enables a process for determining an overall condition of a geographical area as follows:

1. Capturing image data associated with a known location (a geographical area). The images may be captured from, inter alia, traffic cameras, security cameras, personal cameras, etc. The images may be stored in a database (e.g., within image data systems and/or memory system **8**).
2. Analyzing contents within an image for discrete elements aligned to categories representative of various environmental conditions. For example, system **100** may examine each retrieved image for elements (such as, inter alia, streets, buildings, automobiles, plants, etc.) and identify an associated condition (e.g., litter in the street, broken windows in buildings, etc.).
3. Scoring each element relative to an identified “best” and “worst” case state. For example, an image illustrating a street in perfect condition with no garbage in the street may be assigned a score of “1” (i.e., a best state). Likewise, an image illustrating a street with a few potholes and some garbage in the gutters may be assigned a score a “4” (i.e., below average). Additionally, a single image may comprise multiple elements each comprising associated scores.
4. Selecting elements relevant to users. A user may select elements relevant to a subjective view of neighborhood con-

4

ditions. For example, a user may define neighborhood conditions by a condition of buildings and cars with respect to street conditions, tree conditions, etc.

5. Calculating a personalized neighborhood condition score. System **100** calculates a score for each location associated with retrieved image data based on elements and weightings selected by the user.

System **100** may consume different types of input images such as, inter alia:

1. Individual images.
2. A video stream without audio.
3. A video stream that includes audio.
4. A video stream incorporating information from sensors such as, inter alia, a device responding to physical stimulus such as heat, light, sound, pressure, magnetism, and/or a particular motion.

FIGS. **2A-2C** illustrate an implementation example executed by system **100** for enabling a process for determining an overall condition of a geographical area, in accordance with embodiments of the present invention. The process illustrated in FIGS. **2A-2C** retrieves video data from traffic cameras and geo-tagged image data from a smart phone thereby illustrating visual conditions at different locations within a specified geographical area. The visual conditions and ranked on a scale of 1-10 with a score of 1 being a most desirable condition and a score of 10 being a least desirable condition.

FIG. **2A** comprises a retrieved image **200** (i.e., video data) from a first traffic camera at a first location in the geographical area. The image illustrates and identifies the following key conditions: no on street parking **204**, an abandoned car **207**, no street lighting, and a broken window **209** in a building **211**. The key conditions are identified by identifying elements in the image and comparing the elements to a database of stored images. An algorithm is enabled for scoring each of the key conditions against a condition index comprising baseline conditions. The scores comprise values of 1 to 10 with 10 representing a high risk condition and 1 representing a low condition risk. Additionally, an average score across the key conditions is provided. For example, table 1 illustrates the key conditions receiving the following scores:

TABLE 1

Key Condition	Condition Score
No Parking	5
Abandoned Car	9
No Street Lighting	5
Broken Window	10

Additionally, an averaged condition score (i.e., of the condition scores in table 1) of 7.25 is calculated.

FIG. **2B** comprises a retrieved image **200a** (i.e., video data) from a second traffic camera at an additional location in the geographical area. The image illustrates and identifies the following key conditions: graffiti **219**, broken windows **209a** . . . **209n** in a building **211a**, and an unsecured pile of garbage **224**. The following table 2 illustrates the key conditions receiving the following scores:

TABLE 2

Key Condition	Condition Score
Graffiti	7
Broken Windows	10
Garbage	4

## US 9,245,183 B2

5

Additionally, an averaged condition score (i.e., of the condition scores in table 2) of 7 is calculated.

FIG. 2C comprises a retrieved image (i.e., geo-tagged picture data) from a smart phone at an additional location in the geographical area. The image illustrates and identifies the following key conditions: neat lawns 228, maintained trees 232, maintained buildings 242 comprising maintained windows 242a.

The following table 3 illustrates the key conditions receiving the following scores:

TABLE 3

Key Condition	Condition Score
Neat Lawns	1
Maintained Trees	1
Maintained buildings	1
Maintained Windows	1

Additionally, an averaged condition score (i.e., of the condition scores in table 1) of 1.00 is calculated. Additional images and/or data (e.g., text description data) may be used by system 100 for illustrating and identifying additional key conditions such as inter alia, proximities (e.g., to a fire hydrant, busy streets, schools, hospitals, taverns, police or fire departments, manufacturing facilities, service stations, interstate highways, etc.), street conditions, nighttime visibility conditions, etc. Additional aggregate scores may be generated by averaging all of the aforementioned scores and a resulting map may be generated as described infra with respect to FIGS. 3A and 3B.

FIGS. 3A and 3B illustrate maps illustrating conditions of differing geographical areas, in accordance with embodiments of the present invention. The conditions for the geographical areas are generated based on the average aggregate scores of generated by the process described with respect to FIGS. 2A-2C.

FIG. 3A illustrates a street view map 300 describing different conditions of various geographical areas at a street level. An area comprising a condition score of 1 is bordered by dashed lines. An area comprising a condition score of 2 is bordered by dotted lines. An area comprising a condition score of 3 is bordered by alternating dot/dashed lines.

FIG. 3B illustrates a neighborhood/city view map 310 describing different conditions of various geographical areas at a neighborhood or city level. An area comprising a condition score of 1 is bordered by dashed lines. An area comprising a condition score of 2 is bordered by dotted lines. An area comprising a condition score of 3 is bordered by alternating dot/dashed lines. An area comprising a condition score of 4 is bordered by alternating differing sized dashed lines. An area comprising a condition score of 5 is bordered by solid lines.

FIG. 4 illustrates an algorithm detailing a process flow enabled by system 100 of FIG. 1 for performing a process for scoring conditions, in accordance with embodiments of the present invention. Each of the steps in the algorithm of FIG. 4 may be enabled and executed in any order by a computer processor executing computer code. In step 400, a condition index database is configured for scoring a geographical area. In step 402, a historical image is obtained. In step 404, the historical image is stored with a preconfigured image type, a preconfigured condition score, and a specified location identifier. In step 408, it is determined if there are more images for analysis. If in step 408, it is determined that there are more images for analysis then step 402 is repeated. If in step 408, it is determined that there are no more images for analysis then step 410, a steady state mode for analysis is initiated. In step

6

412, an updated image is obtained. In step 414, a matching (or similar) image is retrieved from the index database. In step 416, variance values associated with the images (from steps 412 and 414) are compared. In step 418 it is determined if the variance values comprise a difference sufficient for reevaluation. If in step 418 it is determined that the variance values comprise a difference sufficient for reevaluation then step 412 is repeated. If in step 418 it is determined that the variance values do comprise a difference sufficient for reevaluation then in step 420, condition scores are recalculated. In step 422, the matching image and recalculated condition scores are stored. In step 424, it is determined if there are more updated images for analysis. If in step 424, it is determined that there are more updated images for analysis then step 412 is repeated. If in step 424, it is determined that there are no more updated images for analysis then in step 428, Scores for addresses without images are interpolated. In step 430, a condition score (for each street) in the geographical area is calculated using a standard condition index. The scores are calculated as follows:  $\text{Score} = (\text{sum of house scores}) / (\text{house count}) * \text{factor}(\text{street score})$ . In step 432, a condition score (for each neighborhood) in the geographical area is calculated using a standard condition index. The scores are calculated as follows:  $\text{Score} = (\text{sum of street scores}) / (\text{street count}) * \text{factor}(\text{neighborhood score})$ . In step 434, a condition score (for each city) in the geographical area is calculated using a standard condition index. The scores are calculated as follows:  $\text{Score} = (\text{sum of neighborhood scores}) / (\text{neighborhood count}) * \text{factor}(\text{city score})$ .

FIG. 5 illustrates an algorithm detailing a process flow enabled by system 100 of FIG. 1 for scoring conditions and presenting results, in accordance with embodiments of the present invention. Each of the steps in the algorithm of FIG. 5 may be enabled and executed in any order by a computer processor executing computer code. In step 500, image data associated with multiple locations within a specified geographical area is retrieved (in real time). The image data is retrieved from multiple cameras (e.g., traffic cameras, security cameras, etc.) and/or social media sources. The multiple locations may comprise, city level locations, neighborhood level locations, street level locations, etc. Additionally, non-image data files associated with the multiple locations may be retrieved. In step 502, the image data is compared to stored image data. The stored image data include baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area. Variance associated with differences between attributes of the image data with respect to the stored image data may be determined and compared to a specified threshold to determine further processing. Additionally, the non-image data files are analyzed with respect to an expected condition level of baseline locations within a baseline geographical area. In step 504, user input factors or default factors (associated with geographical condition attributes) are received. In step 506, condition score values associated with the multiple locations are calculated (with respect to the image data) or interpolated (with respect to the non-image data) based on results of steps 502, 504, and 506. The condition score values indicate real time condition values associated with the multiple locations. Additionally, street condition scores associated with streets located within the specified geographical area and neighborhood condition scores associated with neighborhoods comprising the streets are calculated. In step 510, an overall condition score value associated with the specified geographical area is calculated based on the condition score values, street condition scores, and neighborhood condition scores. The overall condition score value may comprise a

US 9,245,183 B2

7

weighted summation of the neighborhood condition scores. In step 512, a map (chart or table) indicating the overall condition score value associated with the specified geographical area is generated and presented to a user. The map (chart or table) may present the overall condition score value as various different attributes (in the specified geographical area) including, inter alia, differing colors, special representations, graphical objects, etc.

FIG. 6 illustrates a computer system 90 used by or comprised by the system of FIG. 1 for enabling a process for scoring conditions and presenting results, in accordance with embodiments of the present invention.

Aspects of the present invention may take the form of an entirely hardware embodiment, an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodiment combining software and hardware aspects that may all generally be referred to herein as a "circuit," "module," or "system."

The present invention may be a system, a method, and/or a computer program product. The computer program product may include a computer readable storage medium (or media) having computer readable program instructions thereon for causing a processor to carry out aspects of the present invention.

The computer readable storage medium can be a tangible device that can retain and store instructions for use by an instruction execution device. The computer readable storage medium may be, for example, but is not limited to, an electronic storage device, a magnetic storage device, an optical storage device, an electromagnetic storage device, a semiconductor storage device, or any suitable combination of the foregoing. A non-exhaustive list of more specific examples of the computer readable storage medium includes the following: a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), a static random access memory (SRAM), a portable compact disc read-only memory (CD-ROM), a digital versatile disk (DVD), a memory stick, a floppy disk, a mechanically encoded device such as punch-cards or raised structures in a groove having instructions recorded thereon, and any suitable combination of the foregoing. A computer readable storage medium, as used herein, is not to be construed as being transitory signals per se, such as radio waves or other freely propagating electromagnetic waves, electromagnetic waves propagating through a waveguide or other transmission media (e.g., light pulses passing through a fiber-optic cable), or electrical signals transmitted through a wire.

Computer readable program instructions described herein can be downloaded to respective computing/processing devices from a computer readable storage medium or to an external computer or external storage device via a network, for example, the Internet, a local area network, a wide area network and/or a wireless network. The network may comprise copper transmission cables, optical transmission fibers, wireless transmission, routers, firewalls, switches, gateway computers and/or edge servers. A network adapter card or network interface in each computing/processing device receives computer readable program instructions from the network and forwards the computer readable program instructions for storage in a computer readable storage medium within the respective computing/processing device.

Computer readable program instructions for carrying out operations of the present invention may be assembler instructions, instruction-set-architecture (ISA) instructions, machine instructions, machine dependent instructions, microcode, firmware instructions, state-setting data, or either

8

source code or object code written in any combination of one or more programming languages, including an object oriented programming language such as Smalltalk, C++ or the like, and conventional procedural programming languages, such as the "C" programming language or similar programming languages. The computer readable program instructions may execute entirely on the user's computer, partly on the user's computer, as a stand-alone software package, partly on the user's computer and partly on a remote computer or entirely on the remote computer or server. In the latter scenario, the remote computer may be connected to the user's computer through any type of network, including a local area network (LAN) or a wide area network (WAN), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider). In some embodiments, electronic circuitry including, for example, programmable logic circuitry, field-programmable gate arrays (FPGA), or programmable logic arrays (PLA) may execute the computer readable program instructions by utilizing state information of the computer readable program instructions to personalize the electronic circuitry, in order to perform aspects of the present invention.

Aspects of the present invention are described herein with reference to flowchart illustrations and/or block diagrams of methods, apparatus (systems), and computer program products according to embodiments of the invention. It will be understood that each block of the flowchart illustrations and/or block diagrams, and combinations of blocks in the flowchart illustrations and/or block diagrams, can be implemented by computer readable program instructions.

These computer readable program instructions may be provided to a processor of a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks. These computer readable program instructions may also be stored in a computer readable storage medium that can direct a computer, a programmable data processing apparatus, and/or other devices to function in a particular manner, such that the computer readable storage medium having instructions stored therein comprises an article of manufacture including instructions which implement aspects of the function/act specified in the flowchart and/or block diagram block or blocks.

The computer readable program instructions may also be loaded onto a computer, other programmable data processing apparatus, or other device to cause a series of operational steps to be performed on the computer, other programmable apparatus or other device to produce a computer implemented process, such that the instructions which execute on the computer, other programmable apparatus, or other device implement the functions/acts specified in the flowchart and/or block diagram block or blocks.

The flowchart and block diagrams in the Figures illustrate the architecture, functionality, and operation of possible implementations of systems, methods, and computer program products according to various embodiments of the present invention. In this regard, each block in the flowchart or block diagrams may represent a module, segment, or portion of instructions, which comprises one or more executable instructions for implementing the specified logical function(s). In some alternative implementations, the functions noted in the block may occur out of the order noted in the figures. For example, two blocks shown in succession may, in fact, be executed substantially concurrently, or the blocks

US 9,245,183 B2

9

may sometimes be executed in the reverse order, depending upon the functionality involved. It will also be noted that each block of the block diagrams and/or flowchart illustration, and combinations of blocks in the block diagrams and/or flowchart illustration, can be implemented by special purpose hardware-based systems that perform the specified functions or acts or carry out combinations of special purpose hardware and computer instructions.

The computer system 90 illustrated in FIG. 6 includes a processor 91, an input device 92 coupled to the processor 91, an output device 93 coupled to the processor 91, and memory devices 94 and 95 each coupled to the processor 91. The input device 92 may be, inter alia, a keyboard, a mouse, a camera, a touchscreen, etc. The output device 93 may be, inter alia, a printer, a plotter, a computer screen, a magnetic tape, a removable hard disk, a floppy disk, etc. The memory devices 94 and 95 may be, inter alia, a hard disk, a floppy disk, a magnetic tape, an optical storage such as a compact disc (CD) or a digital video disc (DVD), a dynamic random access memory (DRAM), a read-only memory (ROM), etc. The memory device 95 includes a computer code 97. The computer code 97 includes algorithms (e.g., the algorithms of FIGS. 4 and 5) for enabling a process for scoring conditions and presenting results. The processor 91 executes the computer code 97. The memory device 94 includes input data 96. The input data 96 includes input required by the computer code 97. The output device 93 displays output from the computer code 97. Either or both memory devices 94 and 95 (or one or more additional memory devices not shown in FIG. 6) may include the algorithms of FIGS. 4 and 5 and may be used as a computer usable medium (or a computer readable medium or a program storage device) having a computer readable program code embodied therein and/or having other data stored therein, wherein the computer readable program code includes the computer code 97. Generally, a computer program product (or, alternatively, an article of manufacture) of the computer system 90 may include the computer usable medium (or the program storage device).

Still yet, any of the components of the present invention could be created, integrated, hosted, maintained, deployed, managed, serviced, etc. by a service supplier who offers to enable a process for scoring conditions and presenting results. Thus the present invention discloses a process for deploying, creating, integrating, hosting, maintaining, and/or integrating computing infrastructure, including integrating computer-readable code into the computer system 90, wherein the code in combination with the computer system 90 is capable of performing a method for scoring conditions and presenting results. In another embodiment, the invention provides a business method that performs the process steps of the invention on a subscription, advertising, and/or fee basis. That is, a service supplier, such as a Solution Integrator, could offer to enable a process for scoring conditions and presenting results. In this case, the service supplier can create, maintain, support, etc. a computer infrastructure that performs the process steps of the invention for one or more customers. In return, the service supplier can receive payment from the customer(s) under a subscription and/or fee agreement and/or the service supplier can receive payment from the sale of advertising content to one or more third parties.

While FIG. 6 shows the computer system 90 as a particular configuration of hardware and software, any configuration of hardware and software, as would be known to a person of ordinary skill in the art, may be utilized for the purposes stated supra in conjunction with the particular computer system 90

10

of FIG. 6. For example, the memory devices 94 and 95 may be portions of a single memory device rather than separate memory devices.

While embodiments of the present invention have been described herein for purposes of illustration, many modifications and changes will become apparent to those skilled in the art. Accordingly, the appended claims are intended to encompass all such modifications and changes as fall within the true spirit and scope of this invention.

What is claimed is:

1. A method comprising:

retrieving in real time, by a computer processor of a computing system, image data associated with a plurality of locations within a specified geographical area;

comparing, by said computer processor, said image data to a plurality of stored image data, wherein said plurality of stored image data comprise baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area;

calculating, by said computer processor based on results of said comparing, condition score values associated with said plurality of locations, wherein said condition score values indicate real time condition values associated with said plurality of locations;

calculating, by said computer processor based on said condition score values, an overall condition score value associated with said specified geographical area; and  
generating, by said computer processor, a map indicating said overall condition score value associated with said specified geographical area.

2. The method of claim 1, wherein said image data are retrieved from a plurality of cameras located within various locations within said specified geographical area.

3. The method of claim 2, wherein said image data are further retrieved from social media sources.

4. The method of claim 1, wherein said results of said comparing indicate a variance between attributes of said image data and attributes of said plurality of stored image data, and wherein said variance exceeds a specified threshold.

5. The method of claim 1, further comprising:

retrieving in real time, by said computer processor, non-image data files associated with said plurality of locations within said specified geographical area;

analyzing, by said computer processor, said non-image data files; and

interpolating, by said computer processor based on results of said analyzing, condition values associated with said plurality of locations, wherein said calculating said condition score values is further based on said condition values.

6. The method of claim 1, wherein said calculating said condition score values comprises:

calculating street condition scores associated with streets located within said specified geographical area and neighborhood condition scores associated with neighborhoods comprising said streets, wherein said overall condition score value comprises a weighted summation of said neighborhood condition scores.

7. The method of claim 1, further comprising:

receiving, by said computer processor from a user, user selections associated with geographical condition attributes, wherein said calculating said condition score values is further based on said user selections.

## US 9,245,183 B2

## 11

8. The method of claim 1, further comprising:  
 presenting, by said computer processor to a user said map,  
 wherein said map presents said overall condition score  
 value as various different attributes in said specified  
 geographical area. 5

9. The method of claim 8, wherein said various different  
 attributes comprise attributes selected from the group consist-  
 ing of colors, special representations, and graphical objects.

10. The method of claim 1, further comprising:  
 providing at least one support service for at least one of 10  
 creating, integrating, hosting, maintaining, and deploy-  
 ing computer-readable code in the computing system,  
 said code being executed by the computer processor to  
 implement: said retrieving, said comparing, said calcul-  
 ating said condition score values, said calculating said 15  
 overall condition score value, and said generating.

11. A computing system comprising a computer processor  
 coupled to a computer-readable memory unit, said memory  
 unit comprising instructions that when executed by the com-  
 puter processor implements a method comprising: 20

retrieving in real time, by said computer processor, image  
 data associated with a plurality of locations within a  
 specified geographical area;  
 comparing, by said computer processor, said image data to  
 a plurality of stored image data, wherein said plurality of 25  
 stored image data comprise baseline measurement val-  
 ues associated with an expected condition level of base-  
 line locations within a baseline geographical area;  
 calculating, by said computer processor based on results of  
 said comparing, condition score values associated with 30  
 said plurality of locations, wherein said condition score  
 values indicate real time condition values associated  
 with said plurality of locations;  
 calculating, by said computer processor based on said con-  
 dition score values, an overall condition score value 35  
 associated with said specified geographical area; and  
 generating, by said computer processor, a map indicating  
 said overall condition score value associated with said  
 specified geographical area.

12. The computing system of claim 11, wherein said image 40  
 data are retrieved from a plurality of cameras located within  
 various locations within said specified geographical area.

13. The computing system of claim 12, wherein said image  
 data are further retrieved from social media sources.

14. The computing system of claim 11, wherein said results 45  
 of said comparing indicate a variance between attributes of  
 said image data and attributes of said plurality of stored image  
 data, and wherein said variance exceeds a specified threshold.

15. The computing system of claim 11, wherein said 50  
 method further comprises:  
 retrieving in real time, by said computer processor, non-  
 image data files associated with said plurality of loca-  
 tions within said specified geographical area;  
 analyzing, by said computer processor, said non-image  
 data files; and

## 12

interpolating, by said computer processor based on results  
 of said analyzing, condition values associated with said  
 plurality of locations, wherein said calculating said con-  
 dition score values is further based on said condition  
 values.

16. The computing system of claim 11, wherein said cal-  
 culating said condition score values comprises:  
 calculating street condition scores associated with streets  
 located within said specified geographical area and  
 neighborhood condition scores associated with neigh-  
 borhoods comprising said streets, wherein said overall  
 condition score value comprises a weighted summation  
 of said neighborhood condition scores.

17. The computing system of claim 11, wherein said  
 method further comprises:  
 receiving, by said computer processor from a user, user  
 selections associated with geographical condition  
 attributes, wherein said calculating said condition score  
 values is further based on said user selections.

18. The computing system of claim 11, wherein said  
 method further comprises:  
 presenting, by said computer processor to a user said map,  
 wherein said map presents said overall condition score  
 value as various different attributes in said specified  
 geographical area.

19. The computing system of claim 18, wherein said vari-  
 ous different attributes comprise attributes selected from the  
 group consisting of colors, special representations, and  
 graphical objects.

20. A computer program product, comprising a computer  
 readable hardware storage device storing a computer readable  
 program code, said computer readable program code com-  
 prising an algorithm that when executed by a computer pro-  
 cessor of a computing system implements a method, said  
 method comprising:  
 retrieving in real time, by said computer processor, image  
 data associated with a plurality of locations within a  
 specified geographical area;  
 comparing, by said computer processor, said image data to  
 a plurality of stored image data, wherein said plurality of  
 stored image data comprise baseline measurement val-  
 ues associated with an expected condition level of base-  
 line locations within a baseline geographical area;  
 calculating, by said computer processor based on results of  
 said comparing, condition score values associated with  
 said plurality of locations, wherein said condition score  
 values indicate real time condition values associated  
 with said plurality of locations;  
 calculating, by said computer processor based on said con-  
 dition score values, an overall condition score value  
 associated with said specified geographical area; and  
 generating, by said computer processor, a map indicating  
 said overall condition score value associated with said  
 specified geographical area.

# U.S. Patent 9,245,183 (Haas) – Claim 1

## Let Zillow See

- As of now, our Zestimates are mainly based on location and size of the properties and they do not consider the **quality**.
- Tax assessment might carry house quality information up to some extent but that's not enough.
  - For example, an interior upgrade would not change the tax assessment in most cases if not all

**Note:** Previously, Zillow's Zestimate did not take into account the quality of a home's attributes.

# U.S. Patent 9,245,183 (Haas) – Claim 1

## 1. A method comprising:

**Zillow Unveils Smarter, More Accurate Zestimate That 'Sees' Unique Home Features, Incorporates Greater Real-Time Data**

Cutting edge neural network and artificial intelligence technologies, combined with the imaginative work of the \$1 million Zillow Prize winners, creates most accurate Zestimate ever

Jun 27, 2019

The Zestimate revolutionized real estate when it launched in 2006, using facts from public records to estimate a home's value. With today's update, it can now, in a sense, "see" in photographs features that humans would instantly understand, such as curb appeal and natural light. The new Zestimate uses neural networks and computer vision to distinguish between high and low-end finishes and to incorporate the value of features like updated bathroom fixtures, fireplaces, and remodeled kitchens. The Zestimate also now uses real-time data from for-sale homes, including list price and how long a home has been on the market.

**Note:** Zillow's updated Zestimate now calculates quality scores for a home based on the images of said home. These quality scores are incorporated into the Zestimate, and ultimately into the Zillow Home Value Index (ZHVI).

Zillow Press Releases, <http://zillow.mediaroom.com/2019-06-27-Zillow-Unveils-Smarter-More-Accurate-Zestimate-That-Sees-Unique-Home-Features-Incorporates-Greater-Real-Time-Data>.

# U.S. Patent 9,245,183 (Haas) – Claim 1

retrieving in real time, by a computer processor of a computing system, **image data** associated with a plurality of locations within a specified geographical area;

Today's launch incorporates winning ideas from Zillow Prize®, a two-year, \$1 million data science competition. For homes listed for sale, the error rate is now less than 2%, meaning half of all Zestimates fall within 2% of the home's eventual sale price. Sellers, listing agents, and homeowners provide photos for the Zestimate to evaluate. Homeowners can claim their home on Zillow to edit, add, or remove photos at any time in just a few simple clicks.

Zillow Press Releases, <http://zillow.mediaroom.com/2019-06-27-Zillow-Unveils-Smarter-More-Accurate-Zestimate-That-Sees-Unique-Home-Features-Incorporates-Greater-Real-Time-Data>.

**Note:** Homeowners and/or agents may upload home photos to their listing on Zillow's website.

Introducing a new and improved Zestimate algorithm,  
<https://medium.com/zg-tech-blog/introducing-a-new-and-improved-zestimate-algorithm-7a5b831712c7>.

Case 2:20-cv-00851-TSZ Document 40-4 Filed 12/02/19 Page 159 of 269

# U.S. Patent 9,245,183 (Haas) – Claim 1

retrieving in real time, by a computer processor of a computing system, **image data** associated with a plurality of locations within a specified geographical area;

**Note:** Zillow updates the Zestimate to reflect new home facts, including home photos.

Wait ... I have 2 bathrooms not 1! If you've looked up your home on Zillow and uttered these words, we've got some great news for you. You can update your home facts, which will now be immediately factored into your home's Zestimate®.

The Zestimate is a starting point in determining your home's value. As a homeowner, you have the ability to claim your home on Zillow and make sure your home facts are correct. And instead of waiting to see whether the updates are significant enough to impact your Zestimate, you'll know right away.

Now You Can Influence Your Zestimate Instantly,  
<https://www.zillowgroup.com/news/influence-zestimate-instantly/>.

To top it off, Zestimates on for-sale homes update with new information in real time. That means home shoppers get an up-to-the-second snapshot of what's going on in the local housing market. When the Zestimate launched in 2006, it was updated monthly, so this is a big leap forward as both buyers and sellers navigate dynamic and ever-changing housing markets.

Your Zestimate Is Now Smarter — and More Accurate, <https://www.zillow.com/blog/zestimate-updates-230614/>.

Case 2:20-cv-00851-TSZ Document 40-4 Filed 12/02/19 Page 160 of 269

# U.S. Patent 9,245,183 (Haas) – Claim 1

retrieving in real time, by a computer processor of a computing system, **image data associated with a plurality of locations** within a specified geographical area;

New to the Zillow iPhone and Zillow iPad apps, you now can take photos of your favorite homes while on-location, touring the homes. While viewing a home's listing page on Zillow, use your device's camera, or upload an image from your photo library, and have it instantly added to the property's photo gallery. Similar to saving a note, adding photos will automatically save the property to your Favorite Homes list, are private (i.e., can only be viewed by the user while logged into a Zillow account) and will be deleted should the home be removed from your Favorite Homes list.

It's a Snap! Take and Upload Home Photos With Zillow iPhone, iPad Apps,  
<https://www.zillowgroup.com/news/its-a-snap-take-and-upload-home-photos-with-zillow-iphone-ipad-apps/>.

We refer to the database as “living” because the information is continually updated by the combination of our proprietary algorithms, synthesis of third-party data from hundreds of sources, and through improvements by us and, importantly, by our community of users. User-generated content from owners, agents and others enriches our database with photos, videos, and additional property information. Individuals and businesses that use Zillow's mobile applications and websites have updated information on more than 80 million homes in our database, creating exclusive home profiles not available anywhere else. Our inimitable database enables us to create content, products and services

Case 2:20-cv-00851-TSZ Document 40-4 Filed 12/02/19 Page 168 of 269

# U.S. Patent 9,245,183 (Haas) – Claim 1

**comparing, by said computer processor, said image data to a plurality of stored image data, wherein said plurality of stored image data comprise baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area;**

"The new Zestimate was inspired by the way the human brain interprets scenes, objects, and images," said Stan Humphries, Chief Analytics Officer and creator of the Zestimate. "It's a big leap forward, because it means the Zestimate can now understand not just a home's facts and figures, but its quality and curb appeal. By training neural networks using the millions of home photos on Zillow, the Zestimate now values the features people are most proud of – like new granite countertops, a remodeled bathroom, or a meticulously landscaped backyard."

Zillow Press Releases, <http://zillow.mediaroom.com/2019-06-27-Zillow-Unveils-Smarter-More-Accurate-Zestimate-That-Sees-Unique-Home-Features-Incorporates-Greater-Real-Time-Data>.

**Note:** Zillow compares the newly uploaded images to the “millions of home photos” on Zillow’s Website, in order to generate quality scores for various features within the new images.

Case 2:20-cv-00851-TSZ Document 40-4 Filed 12/02/19 Page 164 of 269

# U.S. Patent 9,245,183 (Haas) – Claim 1

comparing, by said computer processor, said image data to a plurality of stored image data, **wherein said plurality of stored image data comprise baseline measurement values associated with an expected condition level of baseline locations within a baseline geographical area;**

**Note:** Using its database of home photographs, Zillow trains a convolutional neural network (CNN) in order to establish baseline quality values for various home features associated with different rooms within a home.

From a technical standpoint, incorporating computer vision and advanced machine learning models into the Zestimate algorithm enables us, for first time, to give consumers a more quantitative accounting of the qualitative aspects of their home. We've always known that photos provide consumers a rich source of information about a home's quality. Yet before recent advances in machine learning, there was no way for computers to look at photos of a home and get the same information that humans do. Now, we've taught the Zestimate to discern quality by training convolutional neural networks with millions of photos of homes on Zillow, and asking them to learn the visual cues that signal a home feature's quality. For instance, if a kitchen has granite countertops, the Zestimate now knows — based on the granite countertop's pixels in the home photo — that the home is likely going to sell for a little more.

Introducing a new and improved Zestimate algorithm,

calculating, by said computer processor based on results of said comparing, condition score values associated with said plurality of locations, wherein said condition score values indicate real time condition values associated with said plurality of locations;

We use proprietary automated valuation models that apply advanced algorithms to analyze our data to identify relationships within a specific geographic area between home-related data and actual sales prices. We provide current home value estimates, or Zestimates, on approximately 100 million U.S. homes. Home characteristics, such as square footage, location or the number of bathrooms, are given different weights according to their influence on home sale prices in each specific geographic area over a specific period of time, resulting in a set of valuation rules, or models, that are applied to generate each home's Zestimate.

Zillow, 2018 10-K, *available at* <https://investors.zillowgroup.com/financials/annual-reports-and-proxies/default.aspx>.

**Note:** The new quality scores are used to calculate an updated Zestimate.

calculating, by said computer processor based on said condition score values, an overall condition score value associated with said specified geographical area; and

**Note:** Zillow uses the Zestimates for all homes in a geographic region to calculate the Zillow Home Value Index (ZHVI) for an entire region.

The methodology for ZHVI can be read in detail [here](#), but the one-sentence explanation is that Zillow takes all estimated home values for a given region and month (Zestimates), takes a median of these values, applies some adjustments to account for seasonality or errors in individual home estimates, and then does the same across all months over the past 20 years and for many different geography levels (ZIP, neighborhood, city, county, metro, state, and country). For example, if ZHVI was \$400,000 in Seattle one month, that indicates that 50 percent of homes in the area are worth more than \$400,000 and 50 percent are worth less (adjusting for seasonal fluctuations– e.g. prices tend to be low in December).

Housing Data 101: Why Use the Zillow Home Value Index (ZHVI) Instead of a Median Sale Price Series, <https://www.zillow.com/research/why-zillow-home-value-index-better-17742/>.

## Explore and Update Your Advertising

Once you have made your initial purchase and become a **Premier Agent**, you can browse ZIP codes, check out new opportunities and purchase advertising independently in the **My Ads** section of your profile. In My Ads, you'll have visibility into metrics to help you make the right decisions to fit your business goals. When you see changes in your local market, you can quickly build a presence in new neighborhoods and use your knowledge of your area to seize every opportunity.

## Exploring My Ads

To get to My Ads, you need to log in to your agent account on Zillow.com and access **Agent Hub**. Here's how to do it:

1. [Log in](#) to your agent account on Zillow.
2. In the Agent Hub, **click Advertising**, then My Ads.

**My Ads**

## Key stats in each ZIP code

Before we get into the details of what you can do in the My Ads section, let's cover definitions of some of the key stats and metrics you'll see there.

ZIP	AVG HOME VALUE	EST. LEADS	EST. COST PER LEAD	EST. ROI 6 MONTHS	SHARE OF VOICE	MONTHLY BUDGET
98290	\$443K	21.4	\$102	5.95x	46.6%	\$1,425
9825	\$558K	15.1	\$304	2.34x	67.9%	\$3,109
98155	\$375K	19.2	\$213	2.42x	46.0%	\$1,980
98175	\$558K	2.0	\$114	2.57x	55.5%	\$1,445
<b>Total Budget:</b>						<b>\$7,943.50</b>

- **Average home value:** The average value of homes in a given ZIP code based on the Zillow Home Value Index (ZHVI).
- **Estimated leads:** The estimated average number of leads you'll receive each month over the next six months in a given ZIP code.
- **Estimated cost per lead:** The estimated cost you'll pay for a lead based on current market conditions.
- **Estimated 6-month ROI:** The estimated return on your marketing dollars based on the average home value for that ZIP code, assuming a 2.5 percent buyer agent commission and a 4 percent conversion rate for your leads. You can change these assumptions using the ROI calculator.
- **Share of voice:** The percentage of exposure you'll receive in comparison to other advertisers. Share of voice values may be manually entered above 100 percent to acquire additional leads; doing so may allow you to appear as the only advertising agent on the page.
- **Monthly budget:** The amount you'll be charged every month. You can adjust this value at any time.

## ROI calculator

You can customize your ROI by using our **ROI calculator**, located at the bottom of the My Ads page. Once you do this, your customized ROI is reflected when you browse ZIP codes.

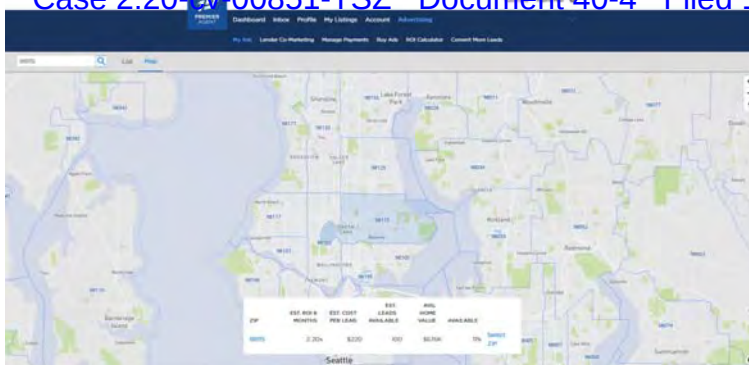

## Browse ZIP codes

Use the **search bar** at the top of the My Ads page to look up information for specific ZIP codes you're interested in. **Enter** a ZIP code to see key ZIP details and compare against ZIP codes in the surrounding area.

## Purchase ZIP codes

**Select** a ZIP code in the map view to reveal more details about costs and competition, including a list of other agents advertising and their share of voice. The slider shows what your share of voice and rank in this ZIP code will be at different budgets.

Once you've settled on a budget, you can easily add it to your cart or check out.

## Make changes to existing advertising

You can add or remove budget in a ZIP code anytime you want in the **Active ZIPs** section. To make changes to your advertising in a ZIP code:

- 1 Click on the **menu icon** on the right side of the ZIP code you want to update.
- 2 Click **Edit**.

This will take you into the ZIP details page, where you can make changes to your advertising. Note that some larger changes to your advertising package may require assistance from a business consultant.

# How do I add or remove photos of my home?

6 months ago · Updated

Follow

To add, remove, or rearrange photos on your home's property page:

- 1. Login to your Zillow profile.
- 2. Make sure you [claimed ownership of your home](#).
- 3. Once you claimed your home's property page, click on the **Owner View** on your property page.
- 4. Under the **More** drop down menu, click **Add Photos**.

- 5. To add photos, click the **Upload photos** button under **Photos & media**.
- 6. You will be prompted to select photo files stored on your computer.
- 7. To remove a photo, click on an individual photo and click **Remove Photo**.

- 8. To rearrange photos, click on the individual photo and hold the left mouse button down. Drag any photo to the desired place in the photo grouping order.
- 9. Save your changes by clicking the **Save Changes** button at the bottom of the page.

To find out how previous photos may have been added to your home's property page, see the help article [How do photos of my home get on Zillow?](#)

Your Zestimate Is Now Smarter - and More Accurate

BY ZILLOW ON 26 JUN 2019

Zestimate’s complex machine learning models examine for more than 100 million homes across the country.

Here's the rundown of what's new.

## 'Seeing' your home features

We can evaluate photos of a home to, in a sense, "see" and value the home features you're most proud of. Think of the bathroom you remodeled, the new quartz countertops in your kitchen or the beautifully landscaped backyard. Those features now factor directly into your home's Zestimate, making it the first time the Zestimate can understand not just a home's facts and figures, like number of bathrooms or bedrooms, but also its quality and curb appeal.

We heard from homeowners over the years that when it comes time to sell, they want to make sure all the work they've put toward upgrading it is reflected in its Zestimate. Yet before recent advances in technology, there was no way for computers to look at photos of a home and get the same information that people do. The Zestimate now incorporates advanced technologies that make this possible.

Homeowners can [claim their home on Zillow](#) to edit, add or remove photos at any time in just a few simple clicks.

## Listing info added in real time

On homes listed for sale, the Zestimate now incorporates data from the home's listing itself — including listing price and how long it has been on the market — in its calculations. These factors provide important insight into a homeowner and agent's listing strategy and what the homeowner believes their home is worth, both key

To top it off, Zestimates on for-sale homes update with new information in real time. That means home shoppers get an up-to-the-second snapshot of what’s going on in the local housing market. When the Zestimate launched in 2006, it was updated monthly, so this is a big leap forward as both buyers and sellers navigate dynamic and ever-changing housing markets.

The results of all these upgrades? The Zestimate’s error rate on homes listed for sale is now less than 2%, meaning half of all Zestimates fall within 2% of the home’s eventual sale price.

Just as you look for new ways to refresh your home, we’re always working to improve the Zestimate. This most recent [Zestimate refresh](#) is another milestone along that journey, all to provide a more accurate look at the value of the place you call home.

I do not buy any of what IMHO is solid put out by this company. The site claims it does not factor in listed sales prices however I have on record with customer service questioning both before and after Zestimate issues, where indeed the so-called "Zestimates" have both increased and lowered right in tandem with a listed sales price. Another thing personal to me they have not provided any logical reason how a property two doors down can have an offer right at listing price AND a Zestimate of \$800,000. above our property two doors down when we have a... Anna Priest

As for me, it's a great project! But people say that the programme can make mistakes and even be unpredictable. As Chris told it underestimates your home, so... Anyway you have to check the results not just twice, but rely on other resources as much as it was before. I mean you have to compare the prices on the market. What to say about other countries except of America! What I love is the sources where you can find a lot of relevant property, so it's easier to compare and estimate the real estate price.

I did an addition, remodel, and many upgrades that cost over \$200k and Zillow dropped the value of my house by \$250k when I updated the info. There was even a permit for the work so public records show the value. The county auditor had no problem with upping my value! My neighbor has his house on the market and is furious with me! If a person doesn't want their house on Zillow they should have that option.

zillow zestimate has my property @150 beckman ave south in battle creek michigan valued at less than half of what its worth. i have updated all info as owner. who the h\_\_\_ can i get a hold of to change this. either get it corrected or don't show my property on your stinking website.

5

3 months ago

dan

how can I get a hold of someone from zillow?

6

3 months ago

Kristen

Oh, not even close. Maybe their metrics work better if you want to give them photos of your remodeling work, or in our case make them aware of the very public greenbelt behind our home that significantly increases its value over their estimates. I keep an eye on the market, and Redfin is much more accurate. The Redfin estimate, at the moment, is approximately 100K more than Zillow. Keep trying...

Chris

My Zestimate is far from accurate. Our house appraised at \$650k when we purchased it from my father in law. He sold it to us at a great price \$175k back in December. I'm guessing because of the purchase price our zestimate plummeted. It's now \$180k but was around \$360k just last month. (Which I don't understand because nothing changed.)

6

4 months ago

Amber

Zillow has an estimate of \$80,000 for my house. We have put improvements on it as well as purchase the house that was in shambles next-door to us. We tore it down and put up a shed. We purchased the house for 165,000., 6 years ago and now this tremendous Drop in price seems totally confusing. How in the world could my home have drop that much when homes around in the neighborhood have not dropped like that??

7

4 months ago

saundra creek

Just entering info for a house I would like to sale. Am I to understand they set the price, you can not?

6

4 months ago

Brian

Well, not so fast with the self-congratulations. Zillow devalued our home and the value dropped precipitously while homes immediately surrounding ours went up on average. Our home's price decline was 6000% greater than the surrounding homes' appreciation TO THE NEGATIVE. As in, the average home went up \$303 and our home declined \$18,467. This is in a cookie-cutter development where no one has made modifications. If Zillow and its algorithms can capriciously and unilaterally devalue an individual's most valuable asset, I think they have an ethical responsibility to provide exception reporting to those homeowners whose financial health is being decimated.... **COORDINATED GEOSPATIAL, LIST-BASED  
AND FILTER-BASED SELECTION****BACKGROUND**

Geospatial and list-based mapping software generally can be useful for presenting users with a list of elements or locations that correspond to a geographic area or region in multiple formats. A map view may provide a visual location of a given element, while a list view may provide specific details for the location according to a purpose of the software.

Such mapping software is frequently used for applications that allow users to view elements related to the specific application, including real estate, and other uses. Providing detailed information related to each element may allow a user to compare results according to filtered results based on a location of each element and details corresponding to the compared elements.

**SUMMARY**

Embodiments of a system are described. In one embodiment, the system is a geospatial and list-based mapping system. The system includes: a mapping engine configured to: present a map display on a display device, wherein the map display includes elements within a viewing area of the map display, wherein the elements include geospatial characteristics; and present a list display on the display device, wherein the list display includes a customizable list having the elements from the map display; and synchronizer configured to: synchronize the map display and the list display to concurrently update the elements according to a user input. Other embodiments of the system are also described. Other embodiments of a method and a computer program product are also described. Other aspects and advantages of embodiments of the present invention will become apparent from the following detailed description, taken in conjunction with the accompanying drawings, illustrated by way of example of the principles of the invention.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 depicts a schematic diagram of one embodiment of a geospatial and list-based mapping system.

FIG. 2 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system of FIG. 1.

FIG. 3 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system of FIG. 1.

FIG. 4 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system of FIG. 1.

FIG. 5 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system of FIG. 1.

FIG. 6 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system of FIG. 1.

FIG. 7 depicts a flowchart diagram of one embodiment of a method for coordinated geospatial and list-based mapping.

Throughout the description, similar reference numbers may be used to identify similar elements.

**DETAILED DESCRIPTION**

It will be readily understood that the components of the embodiments as generally described herein and illustrated in the appended figures could be arranged and designed in a wide variety of different configurations. Thus, the following more detailed description of various embodiments, as represented in the figures, is not intended to limit the scope of the

2

present disclosure, but is merely representative of various embodiments. While the various aspects of the embodiments are presented in drawings, the drawings are not necessarily drawn to scale unless specifically indicated.

The present invention may be embodied in other specific forms without departing from its spirit or essential characteristics. The described embodiments are to be considered in all respects only as illustrative and not restrictive. The scope of the invention is, therefore, indicated by the appended claims rather than by this detailed description. All changes which come within the meaning and range of equivalency of the claims are to be embraced within their scope.

Reference throughout this specification to features, advantages, or similar language does not imply that all of the features and advantages that may be realized with the present invention should be or are in any single embodiment of the invention. Rather, language referring to the features and advantages is understood to mean that a specific feature, advantage, or characteristic described in connection with an embodiment is included in at least one embodiment of the present invention. Thus, discussions of the features and advantages, and similar language, throughout this specification may, but do not necessarily, refer to the same embodiment.

Furthermore, the described features, advantages, and characteristics of the invention may be combined in any suitable manner in one or more embodiments. One skilled in the relevant art will recognize, in light of the description herein, that the invention can be practiced without one or more of the specific features or advantages of a particular embodiment. In other instances, additional features and advantages may be recognized in certain embodiments that may not be present in all embodiments of the invention.

Reference throughout this specification to “one embodiment,” “an embodiment,” or similar language means that a particular feature, structure, or characteristic described in connection with the indicated embodiment is included in at least one embodiment of the present invention. Thus, the phrases “in one embodiment,” “in an embodiment,” and similar language throughout this specification may, but do not necessarily, all refer to the same embodiment.

While many embodiments are described herein, at least some of the described embodiments present a system and method for coordinated geospatial and list-based mapping. Specifically, the system synchronizes a map display and a list display on a display device by concurrently updating elements in the list display that are presented on the map display. The update occurs in response to a user input to filter, select, highlight, or otherwise modify the view in either the map display or the list display. Thus, when one display is modified, the other display may be updated automatically without additional user input.

Some conventional systems present a map display and a list display containing shared elements, such that the map display presents a geographic location of a given element, and the list display presents details about the given element. While this allows the use of some coordination between the list and map displays to compare elements in the displays, conventional systems do not concurrently update the list display and map display. Providing coordinated mapping and concurrent updating for a map display and a list display allows bidirectional interaction between the displays and multiple linked selection and filtering capabilities in the displays.

FIG. 1 depicts a schematic diagram of one embodiment of a geospatial and list-based mapping system. The depicted mapping system 100 includes various components, described in more detail below, that are capable of performing the

US 9,158,789 B2

3

functions and operations described herein. In one embodiment, at least some of the components of the mapping system **100** are implemented in a computer system. For example, the functionality of one or more components of the mapping system **100** may be implemented by computer program instructions stored on a computer memory device **102** and executed by a processing device **104** such as a CPU. The mapping system **100** may include other components, such as a disk storage drive **108**, input/output devices **106**, a mapping engine **110**, a synchronizer **112**, and a display device **114**. Some or all of the components of the mapping system **100** may be stored on a single computing device or on a network of computing devices, including a wireless communication network. The mapping system **100** may include more or fewer components or subsystems than those depicted herein. In some embodiments, the mapping system **100** may be used to implement the methods described herein as depicted in FIG. 7.

In one embodiment, the mapping engine **110** is configured to display a geographic area on a map display **116** on a display device **114** according to a predetermined purpose for the mapping system **100**. For example, the geographic area may be an area selected by a user, such as any part of a mapped region stored on a database. In one embodiment, the mapped region stored on a database may include detailed maps of the world, a specific country, or a specific city. The mapping engine **110** may allow a user to zoom in or out and navigate within the mapped region to focus on different areas within the mapped region. The map display **116** includes a viewing area **118** that displays the visible portion of the mapped region. As the user drags a mouse cursor, zooms, or performs other actions within the viewing area **118**, the portion of the mapped region visible in the viewing area **118** may change.

The map display **116** shows elements **120** that have geospatial characteristics **122**, allowing the elements **120** to be indicated on in the mapped region according to a location of each element **120**. The location for each element **120** may be determined by an address, a coordinate, a combination of both, or some other method of describing the location. Elements **120** may include other geospatial characteristics based on the location. In some embodiments, at least some of the details for an element **120** may be displayed on the map display **116** in response to a user action within the map display **116**, such as a cursor rollover of the corresponding element **120**.

In one embodiment, the mapping engine **110** is also configured to present a list display **124** on the display device **114**. In some embodiments, the map display **116** and the list display **124** are presented side-by-side or in some other simultaneous manner—either on the same display device **114** or on multiple display devices **114**—such that the map display **116** and the list display **124** are visible and usable at the same time. The list display **124** may show a list **126** including details corresponding to the elements **120** shown in the map display **116**. The list **126** may include some or all of the geospatial information for each element **120**.

In one embodiment, the mapping system **100** includes a synchronizer **112** configured to synchronize the data in the map display **116** and the list display **124** according to a user input **128** that modifies either the map display **116** or the list display **124**. For example, the user input **128** may include filtering the elements **120** in either the list display **124** or the map display **116**, selecting an element **120** in either display, or deselecting an element **120** in either display, among other operations. The synchronizer **112** concurrently updates each of the displays when either display is modified or updated to provide bidirectional interaction between the displays.

4

FIG. 2 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system **100** of FIG. 1. While the mapping system **100** is described herein in conjunction with the map display **116** and the list display **124** of FIG. 2, the mapping system **100** may be used in conjunction with any map display **116** or list display **124**.

In one embodiment, the map display **116** and the list display **124** may be presented on a display device **114** in a user interface **200**. The user interface **200** may include a web browser or other application. The map display **116** may allow a user to zoom in or out on the mapped region within the viewing area **118** or to modify the type of geography that is displayed (e.g., satellite view, flat view, road view, etc.). The list display **124** may allow the user to scroll through elements **120** in the list **126**. Mapping systems **100** for Internet applications are generally implemented in conjunction with a search engine to allow the user to search for specific locations or to search for specific elements **120** located within a general area.

A search input may display resulting elements **120** on the map display **116** and the list display **124**. The map display **116** may present the elements **120** in any manner, such as circles displayed within the viewing area **118** in locations of the mapped region that correspond to the physical location of each element **120**. In some embodiments, the map display **116** may present some details for an element **120** when the user rolls over the element **120** with a mouse cursor or clicks on the element **120**. The list display **124** may present the elements **120** and the corresponding details in any manner, such as rows in a spreadsheet format.

FIG. 3 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system **100** of FIG. 1. While the mapping system **100** is described herein in conjunction with the map display **116** and the list display **124** of FIG. 3, the mapping system **100** may be used in conjunction with any map display **116** or list display **124**.

In one embodiment, the list display **124** includes a filter **300** that allows the user to filter content displayed in the list display **124**. Because the synchronizer **112** concurrently updates both displays when a change is made to the content of either display, filtering the content in the list display **124** also filters the content shown in the map display **116**. In some embodiments, the filter **300** may be included in the map display **116**, or separately from the map display **116** and the list display **124** but within the mapping system **100** on some other portion of the display device **114**.

In one embodiment, the filter **300** allows the user to perform an initial search for a given element **120** or instances of elements **120** within the mapped region. In another embodiment, the filter **300** allows the user to refine an initial search according to predetermined categories, keywords, or other filtering methods. The mapping system **100** filters the elements **120** within the mapped region and concurrently updates the map display **116** and the list display **124** to present the filtered elements **120** in both displays. The filtered results may include a default state for the elements **120**, such as selecting all of the filtered elements **120** in both displays, deselecting all of the filtered elements **120** in both displays, or some other default state.

FIG. 4 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system **100** of FIG. 1. While the mapping system **100** is described herein in conjunction with the map display **116** and the list display **124** of FIG. 4, the mapping system **100** may be used in conjunction with any map display **116** or list display **124**.

In one embodiment, the mapping engine **110** is configured to draw a selection area **400** around elements **120** within the

## US 9,158,789 B2

5

viewing area 118 of the map display 116. If none of the elements 120 are currently selected, the mapping engine 110 selects all of the elements 120 within the selection area 400. If all of the elements 120 are currently selected when the selection area 400 is drawn, the mapping engine 110 deselects the elements 120 outside of the selection area 400. When the selection area is drawn, the synchronizer 112 updates the map display 116 and the list display 124 so that all of the selected elements 120 within the selection area 400 are shown in both the map display 116 and the list display 124 in a selected state 402, and all of the deselected elements 120 outside of the selection area 400 are shown in both the map display 116 and the list display 124 in a deselected state 404.

In one embodiment, the deselected state 404 is indicated in the map display 116 by graying out the unselected elements 120. The deselected state 404 may be indicated in the list display 124 by un-checking a check box 406 corresponding to each of the unselected elements 120. In one embodiment, the selected state 402 is indicated in the map display 116 by displaying the selected elements 120 with a given shade or color. The selected state 402 may be indicated in the list display 124 by checking the check box 406 corresponding to each of the selected elements 120. The deselected state 404 and selected state 402 may be indicated in any manner to distinguish the deselected elements 120 from the selected elements 120.

FIG. 5 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system 100 of FIG. 1. While the mapping system 100 is described herein in conjunction with the map display 116 and the list display 124 of FIG. 5, the mapping system 100 may be used in conjunction with any map display 116 or list display 124.

In one embodiment, the user may highlight an element 120 in addition to selecting/deselecting elements 120. The highlighted element 120 may be depicted in a highlighted state 500. The highlighted state 500 may be indicated in map display 116 and the list display 124 by outlining the element 120 and the cells corresponding to the element 120, bolding the element 120 and text corresponding to the element 120, changing a color of the element 120 and the text or cell corresponding to the element 120, or any other manner of highlighting the element 120, such that the element 120 is distinguishable from the selected elements 120 and the deselected elements 120.

In various embodiments, selected elements 120 inside the selection area 400 may be highlighted, deselected elements 120 outside the selection area 400 may be highlighted, or elements 120 anywhere in the viewing area 118 of the map display 116 may be highlighted if no selection area has been chosen. Highlighted elements 120 may allow the user to more easily compare elements 120 within the map display 116 and the list display 124. In some embodiments, multiple elements 120 may be highlighted.

FIG. 6 depicts a schematic diagram of one embodiment of the geospatial and list-based mapping system 100 of FIG. 1. While the mapping system 100 is described herein in conjunction with the map display 116 and the list display 124 of FIG. 6, the mapping system 100 may be used in conjunction with any map display 116 or list display 124.

In one embodiment, the map display 116 and the list display 124 include menu options 600 that open in a box or other menu view in response to a cursor input. The menu options 600 may allow the user to perform various operations within the map display 116 and the list display 124. In one embodiment, the menu options 600 are opened by right-clicking within the map display 116 or the list display 124. The menu options 600 may be shared by the map display 116 and the list

6

display 124, such that the menu options provide interactivity with the elements 120 in both displays. In some embodiments, the menu options 600 may allow the user to perform operations on items selected in the list display 124 or the map display 116. In other embodiments, operations for the selected items may be implemented using buttons or other user interface elements 120 proximate the list display 124 or the map display 116.

FIG. 7 depicts a flowchart diagram of one embodiment of a method 700 for coordinated geospatial and list-based mapping. Although the method 700 is described in conjunction with the mapping system 100 of FIG. 1, embodiments of the method 700 may be implemented with other types of mapping systems 100.

In one embodiment, the method 700 includes presenting 705 a map display 116 and a list display 124 on a display device 114. The map display 116 and the list display 124 may be presented on the display device 114 simultaneously, in some embodiments. The map display 116 may include elements 120 that have geospatial characteristics and may be located within a viewing area 118 of the map display 116. The geospatial characteristics may include data corresponding to the location in a mapped region for the map display 116, such as address information, coordinates, and other data. The elements 120 may also include other descriptive information that may be useful for comparing elements 120 or for identifying specific elements 120. The list display 124 includes a customizable list 126 including the elements 120 from the map display 116. The list 126 may be customized by altering the elements 120 selected or highlighted in the list display 124 or the map display 116, or by altering the portion of the mapped region shown in the viewing area of the map display 116.

The method 700 also synchronizes 710 the map display 116 and the list display 124 to concurrently update the elements 120 according to a user input 128. When the user provides input to the mapping system 100 to make changes to the list display 124, the map display 116, or the elements 120 in either display, the mapping system 100 synchronizes the map display 116 and the list display 124 so that the changes are shown in both displays concurrently. This allows the user to view changes made in either display concurrently across both displays, which provides greater interactivity and selection capabilities.

In one embodiment, the method selects 715 an element 120 in either the map display 116 or the list display 124 and concurrently synchronizes the map display 116 and the list display 124 to present the selected element 120 in both the map display 116 and the list display 124 in a selected state. In one embodiment, the mapping system 100 allows the user to draw 720 a selection area 400 in the viewing area 118 of the map display 116 to select elements 120 within the selection area 400. Elements 120 outside the selection area 400 are deselected 725. The selected elements 120 are presented in the selected state 402 and the deselected elements 120 are displayed in a deselected state 404. The selected state 402 and deselected state 404 may use any manner of highlighting, shading, coloring, or other technique to visually distinguish the selected elements 120 from the deselected elements 120 in the map display 116 and the list display 124. The list display 124 is also updated 730 to indicate the deselected elements 120 outside the selection area 400 in a deselected state 404 and the selected elements 120 in a selected state 402.

In one embodiment, the mapping system 100 allows the user to highlight an element 120 in either the map display 116 or the list display 124. The highlighted element 120 may be displayed in a highlighted state in the map display 116 and the list display 124. The highlighted state may include any man-

US 9,158,789 B2

7

ner of highlighting or otherwise distinguishing the highlighted element 120 from selected elements 120 and deselected elements 120.

In one embodiment, the mapping system 100 allows the user to filter the elements 120 in the map display 116 and the list display 124 according to selected preferences in the map display 116 or the list display 124. The user may open a filter dialog box having one or more filtering fields. When the user chooses a given filter, such as by selecting an option from a drop-down menu or entering a filtering keyword, the map display 116 and the list display 124 are updated to reflect the filtered results.

In one embodiment, the mapping system 100 is configured to display a list of menu options in response to receiving a cursor input in the map display 116 or the list display 124. The list of menu options may be shared by the map display 116 and the list display 124, such that the list of menu options includes the same menu options for both the map display 116 and the list display 124. In one embodiment, the cursor input includes a mouse click, a shortcut key, or other cursor input.

An embodiment of a mapping system 100 includes at least one processor coupled directly or indirectly to memory elements through a system bus such as a data, address, and/or control bus. The memory elements can include local memory employed during actual execution of the program code, bulk storage, and cache memories which provide temporary storage of at least some program code in order to reduce the number of times code must be retrieved from bulk storage during execution.

It should also be noted that at least some of the operations for the methods may be implemented using software instructions stored on a computer useable storage medium for execution by a computer. As an example, an embodiment of a computer program product includes a computer useable storage medium to store a computer readable program that, when executed on a computer, causes the computer to perform operations, including an operation to monitor a pointer movement in a web page. The web page displays one or more content feeds. In one embodiment, operations to report the pointer movement in response to the pointer movement comprising an interaction gesture are included in the computer program product. In a further embodiment, operations are included in the computer program product for coordinated geospatial and list-based mapping.

Although the operations of the method(s) herein are shown and described in a particular order, the order of the operations of each method may be altered so that certain operations may be performed in an inverse order or so that certain operations may be performed, at least in part, concurrently with other operations. In another embodiment, instructions or sub-operations of distinct operations may be implemented in an intermittent and/or alternating manner.

Embodiments of the invention can take the form of an entirely hardware embodiment, an entirely software embodiment, or an embodiment containing both hardware and software elements. In one embodiment, the invention is implemented in software, which includes but is not limited to firmware, resident software, microcode, etc.

Furthermore, embodiments of the invention can take the form of a computer program product accessible from a computer-usable or computer-readable medium providing program code for use by or in connection with a computer or any instruction execution system. For the purposes of this description, a computer-usable or computer readable medium can be any apparatus that can contain, store, communicate,

8

propagate, or transport the program for use by or in connection with the instruction execution system, apparatus, or device.

The computer-useable or computer-readable medium can be an electronic, magnetic, optical, electromagnetic, infrared, or semiconductor system (or apparatus or device), or a propagation medium. Examples of a computer-readable medium include a semiconductor or solid state memory, magnetic tape, a removable computer diskette, a random access memory (RAM), a read-only memory (ROM), a rigid magnetic disk, and an optical disk. Current examples of optical disks include a compact disk with read only memory (CD-ROM), a compact disk with read/write (CD-R/W), and a digital video disk (DVD).

Input/output or I/O devices (including but not limited to keyboards, displays, pointing devices, etc.) can be coupled to the system either directly or through intervening I/O controllers. Additionally, network adapters also may be coupled to the system to enable the data processing system to become coupled to other data processing systems or remote printers or storage devices through intervening private or public networks. Modems, cable modems, and Ethernet cards are just a few of the currently available types of network adapters.

In the above description, specific details of various embodiments are provided. However, some embodiments may be practiced with less than all of these specific details. In other instances, certain methods, procedures, components, structures, and/or functions are described in no more detail than to enable the various embodiments of the invention, for the sake of brevity and clarity.

Although specific embodiments of the invention have been described and illustrated, the invention is not to be limited to the specific forms or arrangements of parts so described and illustrated. The scope of the invention is to be defined by the claims appended hereto and their equivalents.

What is claimed is:

1. A computer program product, comprising:

a non-transitory computer readable storage medium to store a computer readable program, wherein the computer readable program, when executed by a processor within a computer, causes the computer to perform operations for coordinated geospatial and list-based mapping, the operations comprising:

presenting a map display on a display device, wherein the map display comprises elements within a viewing area of the map display, wherein the elements comprise geospatial characteristics, wherein the elements comprise selected and unselected elements;

presenting a list display on the display device, wherein the list display comprises a customizable list comprising the elements from the map display;

receiving a user input drawing a selection area in the viewing area of the map display, wherein the selection area is a user determined shape, wherein the selection area is smaller than the viewing area of the map display, wherein the viewing area comprises elements that are visible within the map display and are outside the selection area;

selecting any unselected elements within the selection area in response to the user input drawing the selection area and deselecting any selected elements outside the selection area in response to the user input drawing the selection area; and

synchronizing the map display and the list display to concurrently update the selection and deselection of

## US 9,158,789 B2

9

the elements according to the user input, the selection and deselection occurring on both the map display and the list display.

2. The computer program product of claim 1, wherein the computer readable program, when executed on the computer, causes the computer to perform additional operations, comprising:

selecting an element in either the map display or the list display; and

concurrently synchronizing the map display and the list display to present the selected element in both the map display and the list display in a selected state.

3. The computer program product of claim 1, wherein displaying elements outside the selection area and within the viewing area in a deselected state further comprises:

deselecting elements outside the selection area in response to determining that all elements in the viewing area are selected before drawing the selection area.

4. The computer program product of claim 3, wherein the computer readable program, when executed on the computer, causes the computer to perform additional operations, comprising:

highlighting an element in either the map display or the list display;

displaying the highlighted element in a highlighted state in the map display and the list display.

5. The computer program product of claim 1, wherein the computer readable program, when executed on the computer, causes the computer to perform additional operations, comprising:

presenting the map display and the list display on the display device simultaneously.

6. The computer program product of claim 1, wherein the computer readable program, when executed on the computer, causes the computer to perform additional operations, comprising:

filtering the elements in the map display and the list display according to selected preferences in the map display or the list display.

7. The computer program product of claim 1, wherein the computer readable program, when executed on the computer, causes the computer to perform additional operations, comprising:

displaying a list of menu options in response to receiving a cursor input in the map display or the list display, wherein the list of menu options is shared by the map display and the list display.

8. A method for coordinated geospatial and list-based mapping, the operations comprising:

presenting a map display on a display device, wherein the map display comprises elements within a viewing area of the map display, wherein the elements comprise geospatial characteristics, wherein the elements comprise selected and unselected elements;

presenting a list display on the display device, wherein the list display comprises a customizable list comprising the elements from the map display;

receiving a user input drawing a selection area in the viewing area of the map display, wherein the selection area is a user determined shape, wherein the selection area is smaller than the viewing area of the map display, wherein the viewing area comprises elements that are visible within the map display and are outside the selection area;

selecting any unselected elements within the selection area in response to the user input drawing the selection area

10

and deselecting any selected elements outside the selection area in response to the user input drawing the selection area; and

synchronizing the map display and the list display to concurrently update the selection and deselection of the elements according to the user input, the selection and deselection occurring on both the map display and the list display.

9. The method of claim 8, further comprising:

selecting an element in either the map display or the list display; and

concurrently synchronizing the map display and the list display to present the selected element in both the map display and the list display in a selected state.

10. The method of claim 8, wherein displaying elements outside the selection area and within the viewing area in a deselected state further comprises:

deselecting elements outside the selection area in response to determining that all elements in the viewing area are selected before drawing the selection area

displaying the selected elements in the map display and the list display in the selected state; and

displaying the deselected elements in the map display and the list display in a deselected state.

11. The method of claim 10, further comprising:

highlighting an element in either the map display or the list display;

displaying the highlighted element in a highlighted state in the map display and the list display.

12. The method of claim 8, further comprising:

presenting the map display and the list display on the display device simultaneously.

13. The method of claim 8, further comprising:

filtering the elements in the map display and the list display according to selected preferences in the map display or the list display.

14. The method of claim 8, further comprising:

displaying a list of menu options in response to receiving a cursor input in the map display or the list display, wherein the list of menu options is shared by the map display and the list display.

15. A geospatial and list-based mapping system, comprising:

a mapping engine configured to:

present a map display on a display device, wherein the map display comprises elements within a viewing area of the map display, wherein the elements comprise geospatial characteristics, wherein the elements comprise selected and unselected elements; and

present a list display on the display device, wherein the list display comprises a customizable list comprising the elements from the map display; and

a synchronizer configured to:

receive a user input to draw a selection area in the viewing area of the map display, wherein the selection area is a user determined shape, wherein the selection area is smaller than the viewing area of the map display, wherein the viewing area comprises elements that are visible within the map display and are outside the selection area;

select any unselected elements within the selection area in response to the user input drawing the selection area and deselect any selected elements outside the selection area in response to the user input drawing the selection area; and

synchronize the map display and the list display to concurrently update the selection and deselection of the

US 9,158,789 B2

11

12

elements according to the user input, the selection and deselection occurring on both the map display and the list display.

16. The system of claim 15, wherein the synchronizer is further configured to: 5

select an element in either the map display or the list display; and

concurrently synchronize the map display and the list display to present the selected element in both of the map display and the list display in a selected state. 10

17. The system of claim 15, wherein the synchronizer is further configured to:

deselecting elements outside the selection area in response to determining that all elements in the viewing area are selected before drawing the selection area. 15

18. The system of claim 17, wherein the synchronizer is further configured to:

highlighting an element in either the map display or the list display;

displaying the highlighted element in a highlighted state in the map display and the list display. 20

19. The system of claim 15, wherein the synchronizer is further configured to: filtering the elements in the map display and the list display according to selected preferences in the map display or the list display. 25

20. The system of claim 15, wherein the computer readable program, when executed on the computer, causes the computer to perform additional operations, comprising:

displaying a list of menu options in response to receiving a cursor input in the map display or the list display, 30 wherein the list of menu options is shared by the map display and the list display.

**ABSTRACT**

A system and method for displaying objects in a plurality of layers. The layers are distinguished from one another using a variety of display attributes in order to emphasize objects in upper layers and de-emphasize objects in lower layers. The display attributes may include use of color (hue, saturation, and value), three dimensional images, fill patterns, and other display techniques. The user is able to change the layering in order to emphasize a different group, or category, of objects and de-emphasize other groups. The layers can be predefined, for example a hardware and software layers, or may be defined by analyzing the attributes corresponding with the objects. Objects and their attributes are stored in a data store, such as a relational database. Predefined layers include one or more of these attributes to use for matching.

## SYSTEM AND METHOD FOR SIMULTANEOUS DISPLAY OF MULTIPLE OBJECT CATEGORIES

### BACKGROUND OF THE INVENTION

#### 1. Technical Field

The present invention relates in general to a method and system for using color and highlighting to display a tree view display. More particularly, the present invention relates to a system and method for providing a non-indented, layered representation of tree view data.

#### 2. Description of the Related Art

One of the highest priorities of information technology (IT) organizations responsible with managing mission-critical computing environments is understanding the various components, or objects, that comprise the business system. With increased computer power and advanced networking equipment and tools, even small businesses often have complex business systems. Managing and understanding these increasingly complex systems is an increasingly challenging task.

As used herein, a "business system" serves the needs of the organization's business functions, such as order entry, marketing, accounts receivable, and the like. A business system may span several dissimilar types of computers and be distributed throughout many geographical locations. A business system, in turn, is typically based upon several application programs. An application program may also span several dissimilar types of computers and be distributed throughout a network of computer systems.

An application typically serves a particular function that is needed by the business system. An individual application program may, or may not, be critical to the business system depending upon the role the application program plays within the overall business system. Using networked computers, an application may span several computer systems. In an Internet commerce system, for example, an application program that is part of the company's order processing business system, may be responsible for serving web pages to users browsing the companies online catalog. This application may use several computer systems in various locations to better serve the customers and provide faster response to customer inquiries.

The application may use some computers running one type of operating system, for example a UNIX-based operating system such as IBM's AIX® operating system, while other computer systems may run another type of server operating system such as Microsoft's Windows NT® Server operating system. Individual computer systems work together to provide the processing power needed to run the business systems and application programs. These computer systems may be mainframes, mid-range systems, workstations, personal computers, or any other type of computer that includes at least one processor and can be programmed to provide processing power to the business systems and applications. Applications also manage an organizations data, stored in databases that may be organized in various fashions. Some database files, such as a customer file, may be used by several applications, while other database files are only used by a single application.

Computer systems, in turn, include individual resources that provide various functionality to the computer systems. For example, a modem is an individual resource that allows a computer system to link to another computer system

2

through an communication network. A router is another individual resource that routes electronic messages between computer systems.

Computers are often linked to one another using a network, such as a local area network (LAN), wide area network (WAN), or other types of networks such as the Internet. By linking computers, one computer can use resources owned by another computer system. These resources can include files stored on nonvolatile storage devices and resources such as printers. Smaller computers used by an individual (client computers) are often linked to more powerful computers, called servers, that provide large file systems, larger processing capabilities, and resources not typically found on client computers. Servers may be larger PCs, workstations, or mainframe computer systems.

Applications, database, computers, and networks are all examples of categories, or groups, of objects used by an organization. Because of the interrelationships between objects, the number of different categories of objects, and the vast number of objects in most organizations, mapping and understanding the business system is a difficult challenge to address. Indeed, any system that has large numbers of objects in many categories with relationships is difficult to conceptually understand using tools available today.

What is needed, therefore, is a way of visually presenting complex information by grouping objects into layers and providing different display attributes to aid the user in distinguishing between the various displayed layers.

### SUMMARY

It has been discovered that objects can be grouped into layers and the individual layers can be displayed using display attributes that identifies a particular layer. The layers can be manipulated by the user in order to have a certain group of objects displayed in a particular layer.

For example, a business system can be broken down into a hardware category and a software category. The user can select which of these categories is displayed in the uppermost, or first, layer and which is displayed in a lower, or second, layer. The objects in the uppermost layer are visually emphasized using a variety of techniques. For example, the uppermost objects may be rendered as 3-dimensional objects, may be larger, and may be colored in a highly saturated manner. Lower level objects are distinguished by altering one or more of the display attributes. For example, a second layer may be displayed in a 2-dimensional, or flat, fashion, and be smaller in proportion to the objects displayed in the first layer.

Relationships between objects can be shown as lines between objects and relationships may span layers. In addition, objects within a particular layer can be visually distinguished to show their dissimilarity with respect to one or more attributes while still maintaining their grouping in the same layer. For example, graphics representing computer systems may all be in the same layer, yet may be colored differently to indicate that certain computers are more powerful than other computers. In order to retrieve information about a particular object, the user can select the object using a mouse or pointing device and details concerning the object are displayed for the user to review and/or edit. The user can re-layer the categories so that the category of objects displayed in one layer are moved to another layer. For example, one view can display the category of hardware objects in a first, or most emphasized, layer and a display the category of software objects in a second, less emphasized, layer. By selecting and moving the software category above the hard-

## US 7,187,389 B2

3

ware category (or by moving the hardware category beneath the software category) the category of software objects is redisplayed in the first most emphasized layer and the category of hardware objects is displayed in the second, less emphasized layer.

The foregoing is a summary and thus contains, by necessity, simplifications, generalizations, and omissions of detail; consequently, those skilled in the art will appreciate that the summary is illustrative only and is not intended to be in any way limiting. Other aspects, inventive features, and advantages of the present invention, as defined solely by the claims, will become apparent in the non-limiting detailed description set forth below.

## BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be better understood, and its numerous objects, features, and advantages made apparent to those skilled in the art by referencing the accompanying drawings. The use of the same reference symbols in different drawings indicates similar or identical items.

FIG. 1 is an example of a layered system view showing hardware components on the first layer and software components on the second layer;

FIG. 2 is an example of a layered system view showing software components on the first layer and hardware components on the second layer;

FIG. 3 is a flowchart for creating objects with properties and relationships that are used in layered views;

FIG. 4 is a flowchart for preparing layers based upon object properties and relationships;

FIG. 5 is a flowchart for displaying objects within two or more layers; and

FIG. 6 is a block diagram of an information handling system capable of implementing the present invention.

## DETAILED DESCRIPTION

The following is intended to provide a detailed description of an example of the invention and should not be taken to be limiting of the invention itself. Rather, any number of variations may fall within the scope of the invention which is defined in the claims following the description.

FIG. 1 shows an example of a layered system view showing hardware components on the first layer and software components on the second layer. System display 100 contains a number of components, or objects, that help describe a business or application system. A system may contain a number of objects that relate to one another. Some of these objects have similar attributes, while other objects may have different attributes but are related in some fashion. Objects are grouped into categories in order to aid the user in viewing and understanding the information that is displayed. For example, categories may include application software, middleware software, network resources, and hardware components. These categories, in turn, can be broken into smaller subcategories depending upon the type of information needed by the user. For example, application software can be divided into database files and application programs.

The example shown in FIG. 1 is of a simple computer system that includes computers networked together and shared software applications residing on some of the computers. The system shown has been divided into two basic categories—a hardware category and a software category. Objects in the hardware category are displayed in one layer while objects in the software category are displayed in

4

another layer. It will be appreciated by those skilled in the art that real world depictions of business systems may be much more complex with a multitude of categories, layers, and hundreds, if not thousands, of objects, while the example shown in FIG. 1 is more simple in order to describe the layering approach and provide increased clarity. In addition, system display 100 is capable of displaying objects in a variety of colors as well providing animation features not captured in a paper based drawing.

In system display 100, the user can select which category is displayed in the first layer or the second layer by selecting tab 103 or tab 106 and moving the tab to the position desired. For example, if the user selects tab 103 and moves it to the right of tab 106, then the hardware category would be displayed in layer 2 and the software category would be displayed in layer 1 (see FIG. 2 for an example). Items shown in layer 1 are emphasized using display characteristics to distinguish the items from those in layer 2. In FIG. 1, items in layer 1 are larger and shown in a three dimensional fashion, while items in layer 2 are smaller and shown in a two dimensional fashion making them look “flat” in comparison to those object in layer 1.

In the example, two network hubs (109 and 112) connected to each other. Each of the hubs has several computers attached. Hub 109 is shown connected to computers 115, 118, 121, 124, 127, and 130, while hub 112 is shown connected to computers 133, 136, 139, 142, 145, and 148. Some of the computers are shown with business applications running off of the computer. Computer 115 is used for application 151, computer 124 is used for application 154, computer 130 is used for application 157, computer 139 is used for application 160, and computer 142 is used for application 163. In addition, various databases, or data stores, are used by the applications. These data stores are also stored on a computer system. Data store 172 is used by application 151 and stored in computer 115, data store 175 is used by application 154 and stored on computer 124, data store 178 is used by application 154 and stored on computer 127, and data store 181 is stored on computer 130 and used by both applications 151 and 157. Data stores 184 and 187 are used by application 160 and stored on computer 139, and data stores 190 and 193 are used by application 163 and stored on computer 142. In FIG. 1, layer 1 includes the hubs and the computers and layer 2 includes the applications and the data stores. Objects that are related to one another have a relationship line indicating the relationship. In an upper level, such as level 1, the relationship lines may be thicker, colored differently, or shown using three dimensional display attributes so that the lines look more like pipes or tunnels. As used herein, “color” includes three variables that may be altered to emphasize or de-emphasize a given object—“hue,” “saturation,” and “value.” Hue is the color in general, such as blue, red, yellow, etc. Saturation is the percentage of hue in the colored object. For example, a gray blue would have a lower saturation than a brilliant blue. Finally, value is the amount of white or black in the colored object, often described as the “lightness” or “darkness” of an object. Manipulating one or more of the three variables that comprise color aids in emphasizing or de-emphasizing the object, thus aiding in distinguishing objects in one layer from those in another.

In addition, other visual attributes can be used to distinguish objects in one layer from those in another. The degree to which an object is opaque or transparent, the proximity (closeness) of objects to one another, shape of objects, anomalous versus common (i.e., one black object appears more visually emphasized than six black objects).

## US 7,187,389 B2

5

Additionally, the objects shown within a particular layer can use visual techniques to distinguish additional characteristics. For example, the computers shown in FIG. 1 could be colored with various shades of red. Lighter red colored computers could indicate computers with less power while computers with more power could be colored more deeply red. In this manner, application loads may be shifted based on the power of the computer being used to host the application.

While the example shown in FIG. 1 is that of a computer system, anything with categories of objects with attributes could be shown using the layered approach. For example, the layered view could be used to display categories of problems that have been reported in a problem tracking system. The first layer could default to the most important problems. A second view of the problem data could show the organizations, or departments, handling errors in the first layer and the problems related to the department in a second layer. In addition, while object size and three dimensional display is used to distinguish between the objects in the layers shown in FIG. 1, other display attributes, particularly color and color saturation, can be used to depict object attributes. In a system where spatial relationships with other layers is important, such as a diagram of the human body, color (hue) can be used to distinguish one layer from another. Layers can then be emphasized by highly saturating the uppermost layers shown and lower layers would be dimmer or duller in appearance. Depending on what categories are of interest would determine layers are emphasized. For example, to view the circulatory system as an upper layer, the red used to show the circulation system would be deeply saturated, while colors used to show the respiratory and digestive systems would be dimmed or dulled. Choosing a different layering order to show the digestive system would cause the circulatory system to be dimmed or dulled and the hue used to depict the digestive system to be highly saturated.

FIG. 2 shows an example of a layered system view showing software components on the first layer and hardware components on the second layer within display window 200. The reference numerals used in FIG. 2 correspond to identify objects in FIG. 1. For example, hub 109 in FIG. 1 corresponds to hub 209 in FIG. 2, computer system 115 in FIG. 1 corresponds to computer system 215 in FIG. 2, application 151 corresponds to application 251, data store 172 in FIG. 1 corresponds to data store 272 in FIG. 2, etc.

While each of the objects shown in FIG. 1 is also shown in FIG. 2, the layering used in FIG. 2 shows the software category objects in layer 1 and the hardware category objects in layer 2. Therefore, the applications (251, 254, 257, 260, and 263) and data stores (272, 275, 278, 281, 284, 287, 290, and 293) are shown larger and in a three dimensional fashion, while the network hubs (209 and 212) and computers (215, 218, 221, 224, 227, 230, 233, 236, 239, 242, 245, and 248) are shown smaller and in a two dimensional, or flat, fashion. FIG. 2, consequently emphasizes or highlights the software components and de-emphasizes the hardware components. A user might use layer display window 200 to analyze the software components. In addition, the user may wish to click on a displayed object to view or change attributes corresponding to the object. Tabs 203 and 206 show the layers being displayed. To change the layers back to those shown in display window 100 (see FIG. 1), the user would select one of the tabs and move it to the position desired.

Other attributes could be shown for objects shown in FIG. 2. For example, the application objects could be colored to

6

indicate they type of application and the data stores could be colored to indicate the size of the data store.

The objects shown in FIGS. 1 and 2 are distinguishable from one another due to display attributes that are not based on the space used to display the objects. In other words, the various layers of objects are displayed using non-spatially distinguishable display attribute, such as color hues, color values, color saturation, size, three dimensional images, animation, shading, fill patterns, line patterns, line weights, opacity, transparency, shape, and object anomaly.

FIG. 3 shows a flowchart for creating objects with properties and relationships that are used in layered views. Processing commences at setup step 300 whereupon an object is created (step 310). The object has one or more properties, for example the type of object, its size, location, capacity, and the like. Some of these properties may be dynamic, such as the object's current capacity, while another property, such as the object's type, may be static. These properties are set in step 320.

An object may have one or more relationships with other objects. These relationships are established in step 330. Relationships may be between objects within the same category or between objects in different categories. Related objects in different categories may be in the same layer as the object or may be in different layers altogether. Relationships may be intrinsically set within an object—for example an application may read from a particular data store. Other relationships, such as which computer system hosts a particular application, may be provided by the user or derived when analyzing the relationships within a particular computer.

The object and its properties and relationships are stored (step 340) in a manner so that the attributes are easily retrievable when gathering information to set up the various display layers. One storage mechanism that may be used is a relational database. In a relational database, a category of objects may be stored in a database table and database fields within the table used to store attributes pertaining to the object. Each object can include a unique identifier so that relationships between objects can be stored using the objects' identifiers.

A determination is made as to whether more objects will be created (decision 350). If more objects are desired, "yes" branch 360 is taken by decision 350 looping back to process the next object. When no more objects need to be created, decision 350 branches to "no" branch 370 and processing ends at 390.

FIG. 4 shows a flowchart for preparing layers based upon object properties and relationships. The system retrieves the first object (step 410) from a memory area or data store, such as the relational database described in FIG. 3. The properties associated with the retrieved object are analyzed (step 420). A determination is made as to whether there are predefined layers that establish the objects placement in a particular layer (decision 430). If there are predefined layers established, decision 430 branches to "yes" branch 435 and the object's properties are matched against the predefined layer attributes to determine which layer to assign to the object (step 440). If there are not predefined layers, decision 430 branches to "no" branch 445 and a layer is dynamically created and assigned to the object (step 450). For example, in the example shown in FIGS. 1 and 2, the object type (hardware or software) may be used as the layering attribute. The object properties could indicate which of the attributes better aggregate the objects based upon the position of the attribute (i.e., attributes in the first columns) or based upon another attribute corresponding to the objects.

US 7,187,389 B2

7

A determination is made as to whether more objects need to be analyzed and placed into layers (decision 460). If more objects need to be analyzed and placed into layers, decision 460 branches to "yes" branch 465 which loops back to process the next object. When all the objects have been processed and placed into layers, decision 460 branches to "no" branch 468.

A determination is made as to whether a default, or starting, order exists for displaying the various layers (decision 470). If a default layer order does exist, decision 470 branches to "yes" branch 472 where the default layer order is read (step 475). On the other hand, if no default layer order exists, "no" branch 478 is taken and a layer order is received from the user (step 480). Additionally, if no default layer order is established, the layers can be randomly displayed and the user can manipulate the layer order to suit his or her needs.

Once the objects are assigned to layers and a layer order has been selected (either by default or by a user selection), the layered objects are displayed on the display screen (predefined process 490, see FIG. 5 for further details). Processing then ends at 495.

FIG. 5 shows a flowchart for displaying objects within two or more layers. The layer number is defined and initialized to zero (step 510). The layer number is then incremented prior to processing the first layer (step 520). The first object within the layer is retrieved (step 530). The display attributes for the first layer are applied to the object (step 540). In addition, display attributes may apply to other object attributes. For example, computers may be in the same layer but displayed with different color variables (hue, saturation, value) depending upon the processing power of the computer system. The object is displayed on the display screen with the applied display attributes (step 550). A determination is made as to whether there are more objects to display within the current display level (decision 560). If there are more objects to display within the current display level, decision 560 branches to "yes" branch 565 which loops back to retrieve and process the next object within the layer. On the other hand, if there are no more objects to display within the layer, decision 560 branches to "no" branch 570.

A determination is made as to whether there are more layers to display (decision 580). In some complex systems with many layers, decision 580 may be triggered (i.e. equal "true") before all the layers are processed so that only some of the possible layers are actually displayed. Additionally, the user may display the number of layers that are displayed to increase or decrease the total number of objects shown on the display at a given time. If there are more layers to display, decision 580 branches to "yes" branch 585 which loops back to increment the layer number and process the objects within the next layer. When there are no more layers to process, decision 580 branches to "no" branch 590 and processing ends at 590.

FIG. 6 illustrates information handling system 601 which is a simplified example of a computer system capable of performing the server and client operations described herein. Computer system 601 includes processor 600 which is coupled to host bus 605. A level two (L2) cache memory 610 is also coupled to the host bus 605. Host-to-PCI bridge 615 is coupled to main memory 620, includes cache memory and main memory control functions, and provides bus control to handle transfers among PCI bus 625, processor 600, L2 cache 610, main memory 620, and host bus 605. PCI bus 625 provides an interface for a variety of devices including, for example, LAN card 630. PCI-to-ISA bridge 635 provides

8

bus control to handle transfers between PCI bus 625 and ISA bus 640, universal serial bus (USB) functionality 645, IDE device functionality 650, power management functionality 655, and can include other functional elements not shown, such as a real-time clock (RTC), DMA control, interrupt support, and system management bus support. Peripheral devices and input/output (I/O) devices can be attached to various interfaces 660 (e.g., parallel interface 662, serial interface 664, infrared (IR) interface 666, keyboard interface 668, mouse interface 670, and fixed disk (HDD) 672) coupled to ISA bus 640. Alternatively, many I/O devices can be accommodated by a super I/O controller (not shown) attached to ISA bus 640.

BIOS 680 is coupled to ISA bus 640, and incorporates the necessary processor executable code for a variety of low-level system functions and system boot functions. BIOS 680 can be stored in any computer readable medium, including magnetic storage media, optical storage media, flash memory, random access memory, read only memory, and communications media conveying signals encoding the instructions (e.g., signals from a network). In order to attach computer system 601 to another computer system to copy files over a network, LAN card 630 is coupled to PCI bus 625 and to PCI-to-ISA bridge 635. Similarly, to connect computer system 601 to an ISP to connect to the Internet using a telephone line connection, modem 675 is connected to serial port 664 and PCI-to-ISA Bridge 635.

While the computer system described in FIG. 6 is capable of executing the invention described herein, this computer system is simply one example of a computer system. Those skilled in the art will appreciate that many other computer system designs are capable of performing the invention described herein.

One of the preferred implementations of the invention is an application, namely, a set of instructions (program code) in a code module which may, for example, be resident in the random access memory of the computer. Until required by the computer, the set of instructions may be stored in another computer memory, for example, on a hard disk drive, or in removable storage such as an optical disk (for eventual use in a CD ROM) or floppy disk (for eventual use in a floppy disk drive), or downloaded via the Internet or other computer network. Thus, the present invention may be implemented as a computer program product for use in a computer. In addition, although the various methods described are conveniently implemented in a general purpose computer selectively activated or reconfigured by software, one of ordinary skill in the art would also recognize that such methods may be carried out in hardware, in firmware, or in more specialized apparatus constructed to perform the required method steps.

While particular embodiments of the present invention have been shown and described, it will be obvious to those skilled in the art that, based upon the teachings herein, changes and modifications may be made without departing from this invention and its broader aspects and, therefore, the appended claims are to encompass within their scope all such changes and modifications as are within the true spirit and scope of this invention. Furthermore, it is to be understood that the invention is solely defined by the appended claims. It will be understood by those with skill in the art that if a specific number of an introduced claim element is intended, such intent will be explicitly recited in the claim, and in the absence of such recitation no such limitation is present. For a non-limiting example, as an aid to understanding, the following appended claims contain usage of the introductory phrases "at least one" and "one or more" to

## US 7,187,389 B2

9

introduce claim elements. However, the use of such phrases should not be construed to imply that the introduction of a claim element by the indefinite articles “a” or “an” limits any particular claim containing such introduced claim element to inventions containing only one such element, even when the same claim includes the introductory phrases “one or more” or “at least one” and indefinite articles such as “a” or “an”; the same holds true for the use in the claims of definite articles.

What is claimed is:

1. A method of displaying layered data, said method comprising:

selecting one or more objects to be displayed in a plurality of layers;

identifying a plurality of non-spatially distinguishable display attributes, wherein one or more of the non-spatially distinguishable display attributes corresponds to each of the layers;

matching each of the objects to one of the layers;

applying the non-spatially distinguishable display attributes corresponding to the layer for each of the matched objects;

determining a layer order for the plurality of layers, wherein the layer order determines a display emphasis corresponding to the objects from the plurality of objects in the corresponding layers; and

displaying the objects with the applied non-spatially distinguishable display attributes based upon the determination, wherein the objects in a first layer from the plurality of layers are visually distinguished from the objects in the other plurality of layers based upon the non-spatially distinguishable display attributes of the first layer.

2. The method as described in claim 1 further comprising: receiving a request from a user to rearrange the layers; rearranging the layers in response to the request, the rearranging including:

re-matching one or more objects to a different layer from the plurality of layers;

applying the non-spatially distinguishable display attributes corresponding to the different layer to the one or more re-matched objects; and

displaying the one or more re-matched objects.

3. The method as described in claim 1 further comprising: reading the objects from a data store; and

reading one or more object attributes corresponding to each object from the data store,

wherein the matching further comprises:

matching the object attributes corresponding to each object to one or more layer attributes corresponding to each layer.

4. The method as described in claim 1 further comprising: creating the objects;

setting one or more object attributes corresponding to each object; and

storing the object and the object attributes in a data store.

5. The method as described in claim 4 further comprising: establishing one or more relationships from at least one of the objects to one or more other objects.

6. The method as described in claim 1 wherein the non-spatially distinguishable display attributes are selected from the group consisting of: color hue, color value, color saturation, size, three dimensional image, animation, shading, fill pattern, line pattern, line weight, opacity, transparency, shape, and object anomaly.

10

7. The method as described in claim 1 further comprising: displaying one or more relationship lines connecting at least one of the objects to one or more other objects.

8. An information handling system comprising:

one or more processors;

a memory accessible by the processors;

a nonvolatile storage area accessible by the processors;

a display screen accessible by the processors; and

a layered data display tool to display layered data on the display screen, the layered data display tool including: logic for selecting one or more objects to be displayed in a plurality of layers;

identification logic to identify a plurality of non-spatially distinguishable

display attributes, wherein one or more of the non-spatially distinguishable display attributes corresponds to each of the layers;

matching logic for matching each of the objects to one of the layers;

applicator logic to apply the non-spatially distinguishable display attributes corresponding to the layer for each of the matched objects;

determination logic for determining a layer order for the plurality of layers, wherein the layer order determines a display emphasis corresponding to the objects from the plurality of objects in the corresponding layers; and

display control logic to display the objects with the applied non-spatially distinguishable display attributes, wherein the objects in a first layer from the plurality of layers are visually distinguished from the objects in the other plurality of layers based upon the non-spatially distinguishable display attributes of the first layer.

9. The information handling system as described in claim 8 further comprising:

a rearranging request received from a user;

rearranging logic to rearrange the displayed layers, the rearranging logic including:

re-matching logic to re-match one or more objects to a different layer from the plurality of layers;

application logic to apply the non-spatially distinguishable display attributes corresponding to the different layer to the one or more re-matched objects; and

display logic to display the one or more re-matched objects.

10. The information handling system as described in claim 8 wherein the non-spatially distinguishable display attributes are selected from the group consisting of: color hue, color value, color saturation, size, three dimensional image, animation, shading, fill pattern, line pattern, line weight, opacity, transparency, shape, and object anomaly.

11. The information handling system as described in claim 8 further comprising:

logic to read the objects from a data store within the nonvolatile storage area; and

logic to read one or more object attributes corresponding to each object from the data store,

wherein the matching logic further comprises:

logic to match the object attributes corresponding to each object to one or more layer attributes corresponding to each layer.

US 7,187,389 B2

11

12. A computer program product stored on a computer usable medium for displaying layered data, said computer program product comprising:

means for selecting one or more objects to be displayed in a plurality of layers;

means for identifying a plurality of non-spatially distinguishable display attributes, wherein one or more of the non-spatially distinguishable display attributes corresponds to each of the layers;

means for matching each of the objects to one of the layers;

means for applying the non-spatially distinguishable display attributes corresponding to the layer for each of the matched objects;

means for determining a layer order for the plurality of layers, wherein the layer order determines a display emphasis corresponding to the objects from the plurality of objects in the corresponding layers; and

means for displaying the objects with the applied non-spatially distinguishable display attributes, wherein the objects in a first layer from the plurality of layers are visually distinguished from the objects in the other plurality of layers based upon the non-spatially distinguishable display attributes of the first layer.

13. The computer program product as described in claim 12 further comprising:

means for receiving a request from a user to rearrange the layers;

means for rearranging the layers in response to the request, the rearranging including:

means for re-matching one or more objects to a different layer from the plurality of layers;

means for applying the non-spatially distinguishable display attributes corresponding to the different layer to the one or more re-matched objects; and

means for displaying the one or more re-matched objects.

12

14. The computer program product as described in claim 12 further comprising:

means for reading the objects from a data store; and

means for reading one or more object attributes corresponding to each object from the data store,

wherein the matching further comprises:

means for matching the object attributes corresponding to each object to one or more layer attributes corresponding to each layer.

15. The computer program product as described in claim 12 further comprising:

means for creating the objects;

means for setting one or more object attributes corresponding to each object; and

means for storing the object and the object attributes in a data store.

16. The computer program product as described in claim 15 further comprising:

means for establishing one or more relationships from at least one of the objects to one or more other objects.

17. The computer program product as described in claim 12 wherein the non-spatially distinguishable display attributes are selected from the group consisting of: color hue, color value, color saturation, size, three dimensional image, animation, shading, fill pattern, line pattern, line weight, opaqueness, transparency, shape, and object anomaly.

18. The computer program product as described in claim 12 further comprising:

means for displaying one or more relationship lines connecting at least one of the objects to one or more other objects.

# U.S. Patent 7,187,389 (Redpath) - Claim 1

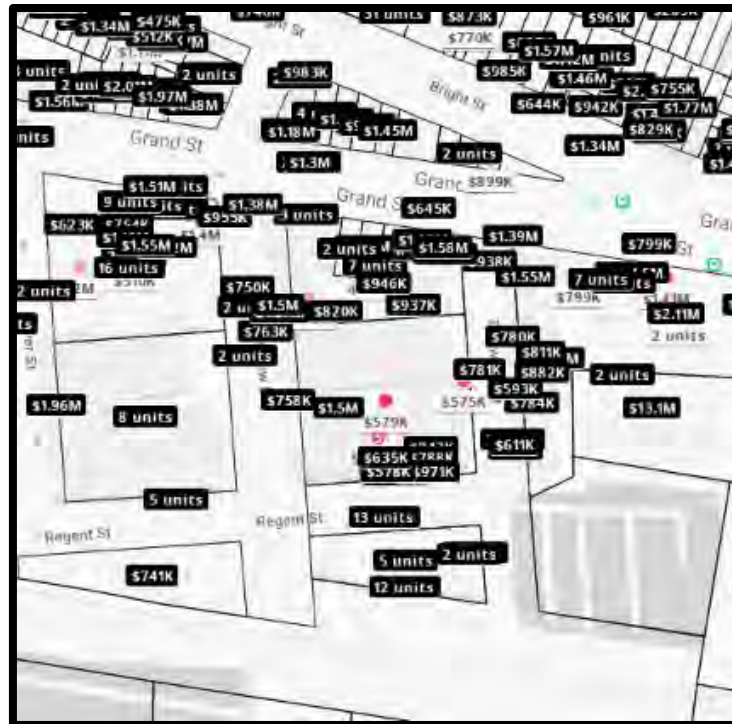

- 1. A method of displaying layered data, said method comprising:**
  - (a) selecting one or more objects to be displayed in a plurality of layers;**
  - (b) identifying a plurality of non-spatially distinguishable display attributes, wherein one or more of the non-spatially distinguishable display attributes corresponds to each of the layers;**
  - (c) matching each of the objects to one of the layers;**
  - (d) applying the non-spatially distinguishable display attributes corresponding to the layer for each of the matched objects;**
  - (e) determining a layer order for the plurality of layers, wherein the layer order determines a display emphasis corresponding to the objects from the plurality of objects in the corresponding layers; and**
  - (f) displaying the objects with the applied non-spatially distinguishable display attributes based upon the determination, wherein the objects in a first layer from the plurality of layers are visually distinguished from the objects in the other plurality of layers based upon the non-spatially distinguishable display attributes of the first layer.**

Case 2:20-cv-00051-TSD Document 40-4 Filed 12/02/19 Page 245 of 269

# U.S. Patent 7,187,389 (Redpath) - Claim 1

## 1. A method of displaying layered data, said method comprising:

**Note:** Zillow displays layered data when a user views property listings and unlisted properties concurrently. The unlisted properties layer is the top layer in the black rectangles, and the “for sale” property listings layer is the lower layer in the red circles.

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

# U.S. Patent 7,187,389 (Redpath) - Claim 1

(a) selecting one or more **objects** to be displayed in a plurality of **layers**;

**Note:** Zillow selects the “for sale” property listings to be displayed in the “for sale” property listings layer and the unlisted properties to be displayed in the unlisted properties layer.

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

Zillow, <https://www.zillow.com/homes>.

# U.S. Patent 7,187,389 (Redpath) - Claim 1

(e) **determining a layer order** for the plurality of layers, wherein **the layer order determines a display emphasis** corresponding to the objects from the plurality of objects in the corresponding layers; and

*Note:* Zillow determines determining that the most recently shown layer will be overlaid over the other layer; the unlisted properties layer is the most recently shown layer on the left whereas the “for sale” property listings layer is the most recently shown layer on the right.

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

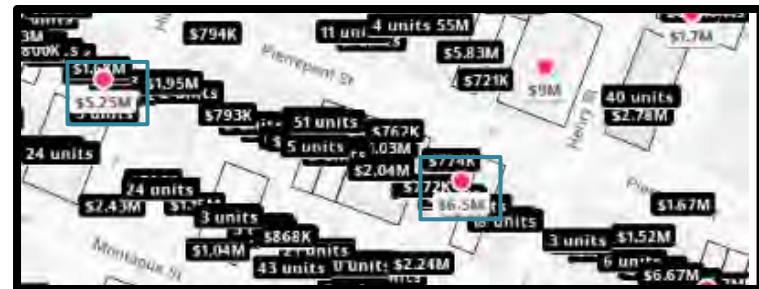

# U.S. Patent 7,187,389 (Redpath) - Claim 1

(e) determining a layer order for the plurality of layers, wherein the layer order determines a display emphasis corresponding to the objects from the plurality of objects in the corresponding layers; and

**Note:** The objects that correspond to the most recently shown layer are determined to be overlaid over the objects that correspond to the other layer; the unlisted properties layer is the most recently shown layer on the left whereas the “for sale” property listings layer is the most recently shown layer on the right.

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

Case 2:20-cv-00051-TSD Document 40-4 Filed 12/02/19 Page 252 of 269

# U.S. Patent 7,187,389 (Redpath) - Claim 1

**(f) displaying the objects with the applied non-spatially distinguishable display attributes based upon the determination, wherein the objects in a first layer from the plurality of layers are visually distinguished from the objects in the other plurality of layers based upon the non-spatially distinguishable display attributes of the first layer.**

**Note:** Zillow displays “for sale” property listings of the “for sale” property listings layer overlaid over the unlisted properties of the unlisted properties layer when the “for sale” property listings layer is the most recently shown layer.

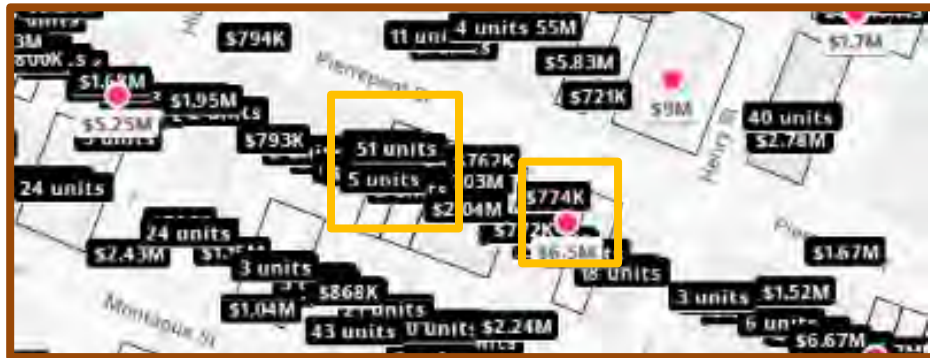

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

Case 2:20-cv-00051-TSD Document 40-4 Filed 12/02/19 Page 253 of 269

# U.S. Patent 7,187,389 (Redpath) - Claim 1

(f) displaying the objects with the applied non-spatially distinguishable display attributes based upon the determination, **wherein the objects in a first layer from the plurality of layers are visually distinguished from the objects in the other plurality of layers based upon the non-spatially distinguishable display attributes of the first layer.**

**Note:** The objects of the unlisted properties layer and the objects of the “for sale” property listings layer are visually distinguished because the unlisted properties are represented by black rectangles and the “for sale” property listings are represented by red circles.

Zillow, [https://www.zillow.com/homes/for\\_sale](https://www.zillow.com/homes/for_sale).

Thank you Hanan for find us our beautiful apartment that we can call it home. You know how we wanted not just house to move but home. You are one of a kind person and I am so happy my little family and I got that lucky to find you. You took our needs and requirements serious and make it priority. I [More](#) ✓
